## PREFACE TO SIXTH EDITION

More than the usual amount of time and effort has been given toward making this new edition of Bergey's Manual useful. The volume has been completely revised and is reset in double column format so that each page carries about 20 per cent more type than the pages in the fifth edition. Those who are interested in special groups of bacteria will find something new in the presentation of the relationships in every genus. Because of our rapidly expanding knowledge, changes in the outline classification and text were made necessary. These changes have in every case been made by specialists in consultation with the Editorial Board. Every specialist possesses first hand knowledge of the species in the group that he or she has reviewed.

Because increasing knowledge has shown the fission fungi to be a larger and more diversified group than previously realized, the number of species described has increased from 1335 in the fifth edition to 1630 in the present edition of the Manual. This number does not cover all of the descriptions found in the literature for, as in all other fields of biology, many of the descriptions are so inadequate that the species described cannot now be identified. Many descriptions are obvious or probable duplications of previous descriptions while still others are based on nothing more substantial than the author's belief that he had something new, he having made but little effort to compare his cultures with those found by previous investigators. An indication of the large number of inadequate descriptions will be found by referring to the material in the appendixes to the various groups, and to the index where synonyms and incompletely described species are shown in italics.

The large number of these poorly described species suggests that there has been much unsatisfactory work done in the field of bacteriological taxonomy. Progress in this inadequately developed field is needed as it would help to clarify the approach to desirable research in many fields of bacteriology.

It is believed that both teachers and investigators will find the new Source and Habitat index useful. It is important to know what organisms have been described from any given habitat in determining the identity of a described species or whether a given species is new.

The future development of taxonomic work holds several interesting possibilities of increased international cooperation such as between the various National Type Culture Collections and within the International

Association of Microbiologists. The Trust Funds provided through the generosity of Dr. Bergey before his death have been used in developing the present edition of the Manual and future funds are to be used in the same way under the management of a self-perpetuating Board of Editor-Trustees.

We are all under obligation to those who have given so freely of their time and special knowledge in preparing this edition of the Manual. Moreover the Editor-in-Chief is under special obligation to his wife, Margaret Edson Breed who has carried the burden of the indexing; to Mrs. Eleanore Heist Clise who has given invaluable service in bibliographical research, in proof reading and other ways; and to his secretary, Miss Maude Hogan, who has cared for many difficult manuscripts and a voluminous technical correspondence.

Many binomials not previously mentioned in the Manual will be found in the Index of Genus and Species Names. Each new name means that there is a new bibliographic reference in the text. Practically all of the incomplete references of previous editions and all new references have been examined in the original, something that is essential in all accurate taxonomic work. The index of names is the most complete list that has appeared in the literature and should always be consulted before new genus or species names are proposed.

This edition of the Manual has been more than four years in press, thanks to the care that has been taken to make it complete and useful. Throughout, the Editorial Board has had the cooperation and understanding help of the publishers of the book who themselves have been forced to meet and overcome the trying difficulties of the war years.

The plan of the present book is such that it will be found useful both to teachers and research workers.

## PREFACE OF FIRST EDITION

The elaborate system of classification of the bacteria into families, tribes and genera by a Committee on Characterization and Classification of the Society of American Bacteriologists (1917, 1920) has made it very desirable to be able to place in the hands of students a more detailed key for the identification of species than any that is available at present. The valuable book on "Determinative Bacteriology" by Professor F. D. Chester, published in 1901, is now of very little assistance to the student, and all previous classifications are of still less value, especially as earlier systems of classification were based entirely on morphologic characters.

It is hoped that this manual will serve to stimulate efforts to perfect the classification of bacteria, especially by emphasizing the valuable features as well as the weaker points in the new system which the Committee of the Society of American Bacteriologists has promulgated. The Committee does not regard the classification of species offered here as in any sense final, but merely a progress report leading to more satisfactory classification in the future.

The Committee desires to express its appreciation and thanks to those members of the society who gave valuable aid in the compilation of material and the classification of certain species. . . .

The assistance of all bacteriologists is earnestly solicited in the correction of possible errors in the text; in the collection of descriptions of all bacteria that may have been omitted from the text; in supplying more detailed descriptions of such organisms as are described incompletely; and in furnishing complete descriptions of new organisms that may be discovered, or in directing the attention of the Committee to publications of such newly described bacteria.

## INTRODUCTION

### SUGGESTIONS FOR THE USE OF THE MANUAL IN CLASSIFYING UNKNOWN ORGANISMS

No organism can be classified before we have determined, through detailed study, its morphological, cultural, physiological and pathogenic characters.

The characters used in the keys to orders, families and genera may ordinarily be determined by the use of a dozen or more of the procedures described in the Manual of Pure Culture Study issued by the Committee on Bacteriological Technic (H. J. Conn, Chairman, Geneva, New York) of the Society of American Bacteriologists. More complete examinations must be made as indicated in the Manual of Pure Culture Study, and in the Descriptive Charts which accompany this Manual where it is desired to identify individual species. These tests must be made if bacteria are to be accurately identified and described.

It is urged that beginning students be taught the technics necessary for the identification of species in the hope that the taxonomic work of the future may be placed on a more satisfactory basis.

After a complete study of the characters of the organism has been made, turn to page 65 and ascertain first in which order the organism belongs. When the order and suborder (if necessary) have been ascertained, turn to the page of the MANUAL on which the key to that order or suborder is given. In this key ascertain the family or subfamily to which the organism belongs.

When the family or subfamily has been decided on, again refer to the page of the MANUAL on which the key to that family or subfamily is given. In this key ascertain the tribe to which the organism belongs.

When the tribe has been decided on, again find the page of the MANUAL on which the key to the tribe is given. In this key ascertain the genus to which the organism belongs.

When the genus has been decided on, again refer to the page of the MANUAL on which the key to that genus is given. In this key, trace out the species under investigation

For example, if one wishes to trace a short, peritrichous, Gram-negative, non-spore-forming rod that grows well on ordinary culture media at 37°C, fermenting glucose and lactose with production of acid and gas, not liquefying gelatin, producing no pigment on any culture medium, with negative reaction for acetylmethylcarbinol, producing indole and reducing nitrates, consult the key to the orders on page 65.

## INTRODUCTION

### SUGGESTIONS FOR THE USE OF THE MANUAL IN CLASSIFYING UNKNOWN ORGANISMS

No organism can be classified before we have determined, through detailed study, its morphological, cultural, physiological and pathogenic characters.

The characters used in the keys to orders, families and genera may ordinarily be determined by the use of a dozen or more of the procedures described in the Manual of Pure Culture Study issued by the Committee on Bacteriological Technic (H. J. Conn, Chairman, Geneva, New York) of the Society of American Bacteriologists. More complete examinations must be made as indicated in the Manual of Pure Culture Study, and in the Descriptive Charts which accompany this Manual where it is desired to identify individual species. These tests must be made if bacteria are to be accurately identified and described.

It is urged that beginning students be taught the technics necessary for the identification of species in the hope that the taxonomic work of the future may be placed on a more satisfactory basis.

After a complete study of the characters of the organism has been made, turn to page 65 and ascertain first in which order the organism belongs. When the order and suborder (if necessary) have been ascertained, turn to the page of the MANUAL on which the key to that order or suborder is given. In this key ascertain the family or subfamily to which the organism belongs.

When the family or subfamily has been decided on, again refer to the page of the MANUAL on which the key to that family or subfamily is given. In this key ascertain the tribe to which the organism belongs.

When the tribe has been decided on, again find the page of the MANUAL on which the key to the tribe is given. In this key ascertain the genus to which the organism belongs.

When the genus has been decided on, again refer to the page of the MANUAL on which the key to that genus is given. In this key, trace out the species under investigation.

For example, if one wishes to trace a short, peritrichous, Gram-negative, non-spore-forming rod that grows well on ordinary culture media at 37°C, fermenting glucose and lactose with production of acid and gas, not liquefying gelatin, producing no pigment on any culture medium, with negative reaction for acetylmethylcarbinol, producing indole and reducing nitrates, consult the key to the orders on page 65.

In this key examine A. *Cells rigid, not flexuous.* This indicates our organism as its cells remain constant in form.

We next examine 1. *Cells single, in chains or masses. Not branching and mycelial in character. Not arranged in filaments. Not acid fast.* As the organism in question occurs as single cells or at most as short chains and is not acid fast, this indicates that it belongs to the Order *Eubacteriales*.

We now examine a. *Do not possess photosynthetic pigments. Cells do not contain free sulfur.* As our organism is unpigmented and the cells do not contain free sulfur, this indicates that our organism belongs to the Sub-order *Eubacteriineae*. We note that the key to this suborder is on page 67.

We next attempt to ascertain the family to which the organism belongs by tracing it through the key to the families of the Sub-order *Eubacteriineae*, p. 67.

I. *No endospores* indicates our organism. We proceed to A. *Can develop on inorganic media.* As the organism cannot grow without organic carbon, we turn to B. *Cannot develop on inorganic media.*

This corresponds with the physiology of our organism; so we turn to 1. *Polar flagellate, etc.* As our organism is peritrichous, we proceed to 2. *Large oval, pleomorphic cells sometimes almost yeast-like in appearance. Free living in soil. Fix free nitrogen.* As this does not correspond with the morphology or physiology of our organism, we next examine 3. *Peritrichous or non-motile rods, and cocci.* This corresponds with the characteristics of our organism.

We turn to a. *Heterotrophic rods which may not require organic nitrogen for growth. Usually motile with one to six or more flagella. Usually form nodules or tubercles on roots of plants, or show violet chromogenesis.*

This again does not indicate our organism; so we turn next to aa. *Heterotrophic rods or cocci which utilize organic nitrogen and usually carbohydrates.* As our rod-shaped organism prefers a medium containing organic nitrogen, we proceed to b. *Spherical cells in masses, tetrads and packets.*

This does not correspond to the morphology of our organism, and we now proceed to bb. *Spherical cells which grow in pairs and chains; and rods.* This includes our rod-shaped organism; so we turn to c. *Gram-positive cocci and rods. Non-motile.* Since these are not the characteristics of our organism, we turn to cc. *Gram-negative rods. When motile, from four to many peritrichous flagella.*

Our organism is Gram-negative and peritrichous; so we proceed to d. *Grow well on ordinary media containing peptone. Aerobic to facultative anaerobic.*

This corresponds with the characteristics of the organism we have studied; so we turn next to e. *Gram-negative, straight rods which ferment*

sugars with the formation of organic acids. This again corresponds with our organism. We turn next to f. *Produce little or no acid from litmus milk*. This does not correspond with the characters we have determined for our organism. We proceed to ff *Produce CO<sub>2</sub> and frequently visible gas (CO<sub>2</sub> + H<sub>2</sub>) from glucose. Reduce nitrates, etc*

Our organism produces visible gas from glucose and reduces nitrates. This indicates that it belongs to *Family X. Enterobacteriaceae*, p. 443.

This appears to fit our unknown organism. We now refer to page 443 on which the key to the Family *Enterobacteriaceae* is found. In this key we ascertain the Tribe to which our organism belongs. 1. *Ferment glucose and lactose with the formation of acid and visible gas. Usually do not liquefy gelatin* Tribe I. *Eschericheae*.

This corresponds with the characters exhibited by our organism. We refer to the key for Tribe I. *Eschericheae* on the same page. 1. *Methyl red test positive. Voges-Proskauer test negative. Salts of citric acid may or may not be used as sole source of carbon. Genus I. Escherichia*, p. 444.

This description appears to correspond with that of our unknown organism. We find the key to the species of Genus *Escherichia* follows the key to the Tribe *Eschericheae*. On tracing our organism in this key we find that it corresponds to *Escherichia coli*. A brief description of this organism is found on the same page.

\* In the use of keys for identifying bacteria, the student is confronted with two difficulties, both based primarily on lack of knowledge and experience. The first is insufficient knowledge concerning the morphology, physiology, possible pathogenicity and habitat of the microorganisms that are to be identified. This may be due to careless observations or to poor training in the special techniques that must be used in determining the identity of a given bacterium

The second difficulty in the use of a key comes from inexperience in the use of technical terms; that is, the student may not thoroughly understand the meaning of the statement in the key and so cannot follow a route through the key with certainty. For example in the keys used here, the student must know the difference (1) between chains of cells which are composed of dividing cells which do not separate at once, and (2) filaments which are composed of dividing cells which remain more permanently together and are normally flattened against each other on adjacent sides. They may show some differentiation into hold fast cells and reproductive cells (conidia), (3) Both chains of cells and filaments are to be distinguished from the mycelial threads found in *Actinomyetaceae*. These are unseptate and branching with a true branching.

\* Condensed and paraphrased from Hitchcock's Descriptive Systematic Botany, New York, 1935.

The student should be warned not to take descriptions in the MANUAL too literally or too rigidly. Descriptions are usually drawn to represent average findings. Especially among bacteria, characters such as sugar fermentations, gelatin liquefaction, presence or absence of flagella and other things will vary. Sometimes these variations are due to slight, possibly unrecognized variations in the techniques used in determining these characters. Real knowledge of the characteristics of species may also be very incomplete. This is true not only of the physiological activities of these microorganisms; but also in regard to such detectable structural features as the number and position of flagella. Dark field movies of motile cells and photographs taken with the recently developed electron microscope are revealing new and heretofore unsuspected facts regarding structural features.

Source and habitat data are frequently helpful in aiding the student to recognize species of bacteria and may indicate that the pathogenicity of the culture in question may need to be tried on some specific animal or plant. By habitat is meant the kind of a place in which the organism normally grows; by source, the particular material and place from which the culture was obtained. This source may or may not indicate the natural habitat. The source of cultures is invariably more limited in scope than the habitat as bacteria normally occur wherever their particular habitat may be found in a world wide distribution.

The student is also reminded that it is impracticable to note all exceptions in keys. Bacteria like other living things are classified according to a combination of characters, not according to some single character, and exceptions to the characters noted in the keys will occur in nature. These may not be known to or may have been overlooked by the author of the key. On the other hand, the importance of such exceptions should not be over-emphasized and the student would do well to use the key as if there were no exceptions.

## HISTORICAL SURVEY OF CLASSIFICATIONS OF BACTERIA, WITH EMPHASIS ON OUTLINES PROPOSED SINCE 1923\*

There have been numerous attempts to arrange the species of bacteria in natural systems of classification. The first simple system of Muller (*Verminum terrestrium et fluviatilium*, 1773) which he developed further a few years later (*Animalcula infusoria fluviatilia et marina*, 1786) listed but two genera (*Vibrio* and *Monas*) that included organisms that would today probably be accepted as bacteria. *Polyangium* Link (Mag. d. Ges. Naturforsch. Freunde zu Berlin, 3, 1809, 42) is apparently the oldest of the generic terms retained in its original meaning for a bacterial genus while *Serratia* Bizio (Biblioteca italiana o sia giornale de lettera, scienze ed arti, 30, 1823, 288) was proposed only fourteen years later.

Systems of classification developed after 1773 are given in complete outline form in the first edition of the MANUAL (1923) and this section of the MANUAL was reprinted without material change in the second (1925) and third (1930) editions. While it is not felt to be necessary to repeat these outlines in their entirety, sufficient reference is made below to permit the student to trace the origin of generic terms that are no longer commonly found in classification outlines. No attempt has been made to include reference to other little used generic terms except as they appear as synonyms in the descriptive portion of the MANUAL. For the origin of generic terms proposed before 1925, see Enlows (*The Generic Names of Bacteria*, Bul. No. 121, Hygienic Laboratory, Washington, D. C., 1920) and Buchanan (*General Systematic Bacteriology*, Baltimore, 1925).

Bory St. Vincent (*Microscopiques, Dictionnaire classique d'histoire naturelle*, 10, 1826, 533) introduced the generic terms *Spirulina*, *Melanella*, *Lactimatoria* and *Pupella* and accepted *Vibrio* for microorganisms, some of which must have been bacteria. None of these terms, except *Vibrio*, are in current use for bacterial groups.

Three of the terms accepted or proposed by Ehrenberg (*Die Infusions-thierchen als vollkommene Organismen*, Leipzig, 1838); namely, *Vibrio*, *Spirillum* and *Spirochaeta*, are still used. The generic term *Bacterium* proposed first by Ehrenberg in 1828 (*Symbolae Physicae seu Icones et Descriptiones Animalium Evertebratorum Separatis Insectis quae ex Itinere per Africam Borealem et Asiam Occidentalem*, IV. *Evertebrata*, Berlin) to include but a single species *Bacterium triloculare* from an oasis

---

\* Contributed by Prof. R. S. Breed, New York State Experiment Station, Geneva, New York, July, 1938; revised, September, 1943.

11th Ann. Rept., 1899, 36), or in his complete outline (Manual Determ. Bact., 1901). Almost all of the generic terms found in his outlines are still in current use.

The term *Aplanobacter* suggested by Erwin F. Smith (Bacteria in Relation to Plant Diseases, 1, 1905, 171, Washington) was accepted by certain American phytopathologists for a time but has never come into general use.

Because other differences between the non-chromogenic and chromogenic micrococci are unimportant, two generic terms, *Albococcus* and *Aurococcus*, suggested by the Winslows (Science, 21, 1905, 669; Systematic Relationships of the Coccaceae, New York, 1908) have not come into general use. They also suggested *Rhodococcus* to include *Rhodococcus roseus* and *R. fulvus* apparently without realizing that Zopf (Ber. d. deutsch. bot. Gesellsch. Berlin, 9, 1891, 28) had previously used the same term for *Rhodococcus erythromyxa* and *R. rhodochrous*. Hansgirg (Engler and Prantl, Die natürlichen Pflanzenfamilien, 1, 1a, 1895, 52) had also used it previously to designate a sub-genus of the green algae, and later Molisch (Die Purpurbakterien, Jena, 1907, 20) used *Rhodococcus* for a genus of the purple bacteria to include *Rhodococcus capsulatus*.

In his complete outline of the classification of bacteria presented in 1909, Orla-Jensen (Cent. f. Bakt., II Abt., 22, 1909, 305) introduced many new generic terms in an effort to create a nomenclature that appeared to him to express the natural relationships of bacteria more satisfactorily than names previously suggested had done. Thus he used the suffixes *coccus* and *sarcina* for spherical bacteria and *monas* for all genera known to be lophotrichous or so related to these types that they were regarded as essentially lophotrichous in nature. In the same way the suffix *bacterium* was used for genera of non-spore-forming rods that were regarded as essentially peritrichous in nature, and the suffix *bacillus* for similar spore-forming rods. As, however, subsequent investigators have (1) accepted the priority rule, (2) felt that it was impossible to recognize the type of motility found in the ancestry of truly non-motile groups, or (3) felt that other characters were more fundamental than those selected by Orla-Jensen, many of these terms have not been generally used by later workers.

Among the little used terms suggested or accepted by Orla-Jensen are: *Acetimonas*, *Nitromonas*, *Azotomonas*, *Rhizomonas*, *Corynemonas*, *Mycomonas*, *Sulfomonas*, *Thiomonas*, *Thiococcus*, *Rhodomonas*, *Rhododictyon*, *Amoebomonas*, *Rhodopolycoccus*, *Rhodosarcina*, *Spirophyllum*, *Denitromonas*, *Liquidomonas*, *Liquidovibrio*, *Liquidococcus*, *Solidococcus*, *Solidovibrio*, *Sporosarcina*, *Denitrobacterium*, *Caseobacterium*, *Liquidobacterium*, *Urobacillus*, *Butyribacillus*, *Pectobacillus*, *Cellulobacillus*, *Putribacillus* and *Botulobacillus*.

While *Nitromonas* is not new, it is redefined as a synonym of *Nitrobacter* Winogradsky (Arch. Sci. Biol. St. Petersburg, 1, 1892, 87), rather than as a synonym of *Nitromonas* Winogradsky (Ann. Inst. Past., 3, 1890, 258). *Spirophyllum* is from Ellis (Cent. f. Bakt., II Abt., 19, 1907, 507).

In a later monograph on The Lactic Acid Bacteria (Mém. d. Acad. Roy. Sci. et Lettres de Danemark, Sect. Sci., 8 Sér., 5, 1919, No. 2) Orla-Jensen proposes the following additional generic terms: *Betacoccus*, *Betabacterium*, *Streptobacterium*, *Thermobacterium* and *Microbacterium*. The term *Tetracoccus* is introduced with a meaning different from that given the term previously by v. Klecki (Cent. f. Bakt., 15, 1894, 354).

Buchanan prepared an outline classification in 1916 (Jour. Bact., 1, 1916, 591; 2, 1917, 155, 347, 603, 3, 1918, 27, 175, 301, 403, 461, 591) which was utilized in part by the group of which he was a member (Winslow, Broadhurst, Buchanan, Krumwiede and Smith) in their preliminary Report to the Society of American Bacteriologists (Jour. Bact., 2, 1917, 552) and in the final report by Winslow, Broadhurst, Buchanan, Krumwiede, Rogers and Smith (Jour. Bact., 5, 1920, 191).

Although prepared earlier, some parts of the Buchanan outline were not published until after the first Winslow et al. report. As these reports formed the most important basis for the classification used in the first edition of the MANUAL, it is natural that the generic terms utilized are, in general, the same as those used in the MANUAL.

Generic and subgeneric terms included by Buchanan that are not used in the present edition of the MANUAL are: *Paraspirillum* Dobell (Arch. f. Protistenk., 24, 1911, 97), *Eubacillus* Hansgirg (Osterr. Bot. Ztschr., 38, 1888, 264; not *Eubacillus* Dangeard, Le Botaniste, 2, 1891, 151) and *Metabacterium* Chatton and Perard (Comp. rend. Soc. Biol., Paris, 65, 1913, 1232). *Siderocapsa* Molisch (Ann. Jard. Bot. Buitenzorg, Ser. 2, Supp. 3, 1909, 29) used by Buchanan but dropped by Winslow et al (Jour. Bact., 2, 1917, 549) does not appear in the MANUAL classification outline until the present (6th) edition. The term *Mycoderma* recognized both by Buchanan (Jour. Bact., 3, 1918, 45) and in the preliminary Winslow et al. report (Jour. Bact., 2, 1917, 551) was replaced by the later and more valid term *Acetobacter* in the final report by Winslow et al. (Jour. Bact., 5, 1920, 201). *Pfeifferella* Buchanan (Jour. Bact., 3, 1918, 51) which is used in the three outline classifications under discussion and also in the first, second and third editions of the MANUAL, appeared in the literature through a clerical error (Buchanan, General Systematic Bacteriology, 1925, 420). It was combined in the fourth edition of the MANUAL with the genus *Actinobacillus* under the latter name. *Nocardia* Trevisan (1889) used by Buchanan and in the preliminary report by Winslow et al. (1917) was merged with *Actinomyces*

Harz (Jahresber. München. Thierarzneisch. for 1877-78, 125) in the final report by Winslow et al. *Erythrobacillus* Fortineau (Compt. rend. Soc. Biol. Paris, 58, 1905, 104) is used by Winslow et al. (1920) but was not accepted in the first and following editions of the MANUAL as it is a synonym of the older *Serratia* Bizio (1823). Moreover, the species which must be accepted as type for the genus (*Erythrobacillus pyosepticus* Fortineau (monotypy)) is a species which has been reported by Breed (Manual, 3rd ed., 1930, 117) to be a variant of the older *Serratia marcescens*.

One of the most unsatisfactory portions of recent classifications, such as those outlined by Buchanan (1917-18) and by Winslow et al. (1917), is the treatment given the organisms of the coliform-dysentery-typhoid group in that the term *Bacterium* is retained for these as suggested by Orla-Jensen (1909). A strict limitation of *Bacterium* to this group gives it a still different meaning from that which it had had in previous and current classifications, and makes it necessary to find some other place for many other species of Gram-negative, non-spore-forming rods, some of which are well known and well described. The relationships of these miscellaneous species to other non-spore-forming rods is frequently poorly understood. In some cases, further study will probably show that they should be placed in well known and currently recognized genera. In others, further study will probably show that some of these species of non-spore-forming rods should be grouped in new genera.

Winslow et al. (1920) recognized this situation and broadened their definition of *Bacterium* thereby placing such well known species as are included in the colon-dysentery-typhoid group with other species of non-spore-forming rods of quite a different character. For this reason, partial use was made in the first edition of the MANUAL of the numerous generic terms newly proposed by Castellani and Chalmers (Manual of Tropical Medicine, 3rd ed., 1919). Thus the following new terms were introduced: *Alcaligenes*, *Salmonella*, *Escherichia* and *Encapsulatus*; and the earlier terms *Aerobacter* Beijerinck (1900) and *Eberthella* Buchanan (1918). Later it was found that *Encapsulatus* was a synonym of *Klebsiella* Trevisan (1887), so that the latter term was accepted in the second and subsequent editions of the MANUAL. *Shigella* Castellani and Chalmers was recognized as distinct from *Eberthella* in the third and subsequent editions.

Many of the new terms suggested by Castellani and Chalmers were, however, synonyms of earlier valid terms or have not been considered necessary, and so they have not come into general use. These are *Nigrococcus*, *Graciloides*, *Cloaca*, *Eberthus*, *Dysenteroides*, *Lankoides*, *Wesenbergus*, *Balkanella* and *Enteroides*. No new generic terms are given by Castellani and Chalmers in their later report (Ann. Inst. Past., 34, 1920, 600).

Orla-Jensen (Jour. Bact., 6, 1921, 263), in a paper published after the manuscript of the first edition of the Manual was prepared, suggested the use of *Colibacterium* and *Aerogenesbacterium* for the two genera in the coliform group and adds quite a number of other new terms formed in accordance with his system of nomenclature. These are, in most cases, synonyms of earlier valid names. The new terms are *Coccomonas*, *Spiromonas* (used in a new, different sense from that of earlier authors), *Fluoromonas*, *Photomonas*, *Propionicooccus*, *Butyriclostridium* and *Putriclostridium*.

Many new terms are proposed in the classification drawn up by Heller (Jour. Bact., 6, 1921, 521; and 7, 1922, 1). Details are given in the group of anaerobic spore-formers only. Here each of the new generic terms is based on a single species. The following outline is given in the first of these papers, two new genera (*Rivoltillus* and *Melchnikovillus*) being made the type genera for two new subfamilies *Clostridioideae* and *Putrificoideae*, respectively.

Phylum I. *Bacteria*

Class I. *Eubacterieae*

Order 1 *Eubacteriales*

Family 6 (?). *Clostridiaceae*

Subfamily 1. *Clostridioideae*

Subfamily 2. *Putrificoideae*

Order 2 *Thiobacteriales*

Order 3. *Chlamydobacteriales*

Class II. *Myxobacterieae*

In the more complete outline in the second paper, one generic term (*Clostridium*) is old, although it is used in a new and restricted sense, while with the exception of the type genera mentioned above, the other terms are new. In the subfamily *Clostridioideae*, the new terms are *Omeliaskillus*, *Macintoshillus*, *Douglasillus*, *Henrillus*, *Flemingillus*, *Vallorillus*, *Multi-fermentans*, *Hiblerillus*, *Welchillus*, *Stoddardillus*, *Arloingillus*, *Meyerillus* and *Novillus*. Ten new generic terms are used in the subfamily *Putrificoideae* as follows: *Sequinillus*, *Regillus*, *Robertsonillus*, *Nicolaerillus*, *Martellillus*, *Recordillus*, *Tissierillus*, *Putrificus*, *Ermengemillus*, and *Weinbergillus*. As there does not seem to be any good reason for sub-dividing the genus *Clostridium* in this way, the latter term has been used to cover anaerobic spore-forming rods in all previous editions of the MANUAL, and is again used in the present edition in this sense rather than with the restricted meaning proposed by Heller.

Enderlein (Sitzber. Gesell. Naturf. Freunde, Berlin, 1917, 309) proposed an outline classification covering the Kingdom of *Mychota*, or bacteria, which was based on comparative morphology with special emphasis on life cycles. This was as follows:

Phylum I. *Dimyckota*Kreis A. *Holocyclomorpha*Class I. *Gonascota*Order a. *Synascota*Family 1. *Schaudinnidae*Genus a. *Schaudinnum*b. *Theciobacterium*Family 2. *Sphaerotilidae*Genus a. *Phragmidiothrix*b. *Newskia*c. *Chlamydothrix*d. *Sphaerotilus*e. *Clonothrix*Family 3. *Syncrotidae*Genus a. *Crenothrix*b. *Beggiatoa*c. *Syncrotia*d. *Zygostasis*Family 4. *Spirillidae*Genus a. *Gallionella*b. *Spirillum*c. *Dicrospirillum*Family 5. *Spirochaetidae*Genus a. *Cristispira*b. *Treponema*c. *Entomospira*d. *Spirochaeta*e. *Cacospira*Family 6. *Microspiridae*Genus a. *Spirobacillus*b. *Spirosoma*c. *Photobacterium*d. *Microspira*e. *Dicrospira*Family 7. *Corynebacteriidae*Subfamily 1. *Actinomycinae*Genus a. *Actinomyces*Subfamily 2. *Eisenberginae*Genus a. *Eisenbergia*Subfamily 3. *Sclerotrichinae*Genus a. *Zettnowia*b. *Schlerothrix*Subfamily 4. *Corynebacteriinae*Genus a. *Corynebacterium*b. *Heterocystia*c. *Cladascus*d. *Zygoplagia*Subfamily 5. *Pseudostrepinae*Genus a. *Pseudostreptus*Order b. *Ascota*Family 8. *Bacteriidae*

- Genus a. *Atremis*
- b. *Bacterium*
- c. *Lamprella*
- d. *Eucystia*
- e. *Dicrobactrum*
- f. *Acystia*
- Family 9. *Fusiformidae*
- Genus a. *Fusiformis*
- Class II *Sporascota*
- Order a *Parasynascota*
- Family 10. *Migulanidae*
- Genus a. *Migulanum*
- Order b. *Parascota*
- Family 11 *Bacillidae*
- Genus a. *Rhagadascia*
- b. *Plectridium*
- c. *Bacillus*
- d. *Bactrillum*
- e. *Kochella*
- f. *Fischerinum*
- Kreis B *Hemicyclomorpha*
- Class I. *Anascota*
- Family 12 *Hemallosidae*
- Genus a *Hemallosis*
- Phylum II. *Monomychota*
- Kreis A *Acyclomorpha*
- Family 1. *Mogallidae*
- Genus a. *Mogallia*
- Family 2 *Sarcinidae*
- Genus a. *Diplococcus*
- b. *Sarcina*
- c. *Paulosarcina*
- Family 3. *Micrococcidae*
- Genus a. *Micrococcus*
- b. *Planococcus*
- c. *Streptococcus*
- d. *Phacelium*

Three of the new generic terms, *Cladascus* type species *C. furcabilis* Enderlein, *Zygoplagia* type species *Z. alternans* Enderlein and *Heterocystia* type species *H. multiformis* Enderlein, had been proposed in an earlier paper (Sitzber. Gesell. Naturf. Freunde, Berlin, 1916, 395). The following generic terms in the 1917 outline are new: *Schaudinnium*, *Theciobactrum*, *Syncrotis*, *Zygostasis*, *Dicrospirillum*, *Entomospira*, *Cacospira*, *Dicrospira*, *Eisenbergia*, *Zettnowia*, *Pseudostreptus*, *Atremis*, *Lamprella*, *Eucystia*, *Dicrobactrum*, *Acystia*, *Migulanum*, *Rhagadascia*, *Kochella*, *Fischerinum*, *Hemallosis*, *Mogallia*, *Paulosarcina* and *Phacelium*. Note that *Corynobacterium* is spelled with an o instead of an e.

Terms accepted from earlier workers that have not previously been

mentioned are: *Spirobacillus* Metschnikoff (Ann. Inst. Past., 3, 1889, 62), *Photobacterium* Beijerinck, Maanblad voor Natuurwetenschappen Amsterdam, 16, 1889, 1 and Arch. Néerl. d. Sci. Exactes, 23, 1889, 401), and *Sclerothrix* Metschnikoff (Arch. f. Path. Anat. u. Physiol., 113, 1888, 63-94; not *Sclerothrix* Kuetzing, Species Algarum, 1849, 319).

The above outline was changed in 1925, p. 235 ff. (Bakterien-Cyclogenie, Berlin, 390 pp.) by the addition of one new family, *Chondromycidae*, to include the genus *Newskia*, formerly included in *Sphaerotilidae*, and nine genera not previously given as follows: *Chondromyces*, *Cystodesmia*, *Monocystia*, *Ophiocystia*, *Apelmocoena*, *Polyangium*, *Cystococcia*, *Myxococcus* and *Dactylocoena*. All except *Chondromyces*, *Polyangium* and *Myxococcus* are taken from Enderlein (Bemerkungen zur Systematik der Chondromyciden, Berlin, 1924, 6 pp.).

The new genus *Lohnisium* is added in the Family *Eisenbergiinae* to include the acetic acid and legume bacteria, and he also proposes the generic term *Macrocystita* (p. 278) for certain bacteria described by Peklo (O mšici krváve (Study of the blood louse). Zemědělského Archivu (Agricultural Archives), 1, 1916) from aphids. According to Enderlein it is not clear whether this genus should be included in the Family *Bacteriidae* or in *Corynebacteriidae*.

Two genera proposed by others are also accepted. These are *Calymmatobacterium* Aragão and Vianna (Mem. Inst. Oswaldo Cruz, 6, 1912, 211) placed in the family *Migulanidae*, and *Leuconostoc* Van Tieghem placed in the family *Micrococcidae*.

Later Enderlein (Sitzber. Gesell. Naturf. Freunde Berlin, 1930, 104-105) accepts *Serratia* Bizio in place of *Dicrobactrum* and *Leptotrichia* Trevisan in place of *Syncrotis*. *Streptus* with *Streptus scarlatinae* as type species, is proposed to cover the streptococci not included in *Pseudostreptus*.

The outline suggested by Pringsheim (Lotos, 71, 1923, 357) is similar to that used by Lehmann and Neumann (Atlas und Grundriss der Bakteriologie, 2 vols, 1896, München). It is a conventional division into spherical, rod-shaped and curved forms so far as the true bacteria are concerned except that the pseudomonads are included in the same family as the vibrios and spirilla. *Rhodobacterales* is recognized as an order to include the sulfur purple bacteria and the nonsulfur purple bacteria. Few details are given in regard to the other orders. His outline follows:

*Schizomycetes*

Order I. *Eubacterales*

Family 1. *Coccaceae*

Genus a. *Streptococcus*

b. *Micrococcus*

c. *Sarcina*

- Family 2. *Bacteriaceae*
  - Genus a. *Bacterium*
  - b. *Bacillus*
- Family 3 *Spirillaceae*
  - Genus a *Pseudomonas*
  - b *Vibrio*
  - c *Spirillum*
- Order II *Rhodobacterales*
  - Family 1 *Rhodobacterinae*
  - 2 *Thiorhodinae*
- Order III *Myxobacterales*
  - Family 1 *Myxobacteriaceae*
- Order IV. *Mycobacterales*
  - Family 1 *Corynebacteriaceae*
  - 2. *Mycobacteriaceae*
  - 3. *Actinomycetaceae*
- (Also possibly the long rod, lactic acid bacteria )
- Order V *Desmobacterales*
  - Family 1 *Chlamydobacteriaceae*
  - 2 *Begoniaceae*

The first outline classification drawn up by Janke (Allgemeine Technische Mikrobiologie, I Teil, Dresden, 1924, p. 63) is an adaptation and expansion of that drawn up by Migula (System der Bakterien, 1900). The new genera recognized by Janke are *Planostreptococcus* A. Meyer (Die Zelle der Bakterien, Jena, 1912), *Thioploca* Lauterborn (Ber. dtsch. Bot. Gesell., 25, 1907, 238), *Thiobacterium* Molisch (Cent. f. Bakt., II Abt., 33, 1912, 55), *Thiobacillus* Beijerinck (Cent. f. Bakt., II Abt., 11, 1904, 593), *Thiovibrio* Janke (*loc. cit.*), *Thiospirillum* Winogradsky (Beitrage zu Morphol. u. Physiol. d. Bakterien. Heft I. Schwefelbakterien. Leipzig, 1888), *Thiosphaerella* Nadson (Bull. Jar. bot Petersburg, 13, 1913, 106; ref. in Cent. f. Bakt., II Abt., 43, 1915, 469), *Thiovulum* Hintze (Ber. Dtsch. Bot. Gesell., 31, 1913, 189), *Spirophyllum* Ellis (Proc. Roy. Soc. Edinburgh, 27, I, 1907, 21; ref. in Cent. f. Bakt., II Abt., 19, 1907, 502), *Nodofolium* Ellis (Cent. f. Bakt., II Abt., 26, 1910, 321), and *Actinococcus* Beijerinck (Fol. Microbiol., 2, 1914, 185)

Janke's outline classification is given below:

- Order I. *Eubacteria*
  - Family 1. *Coccaceae*
    - Genus a. *Streptococcus*
    - b. *Micrococcus*
    - c. *Sarcina*
    - d. *Planostreptococcus*
    - e *Planococcus*
    - f. *Planosarcina*
  - Family 2. *Bacteriaceae*
    - Genus a. *Bacillus*
    - b. *Bacterium*

Family 3. *Spirillaceae*

- Genus a. *Microspira*
- b. *Spirillum*
- c. *Spirosoma*

Order II. *Rhodobacteria*Family 1. *Thiorhodaceae*Subfamily 1a. *Thiocystaceae*

- Genus a. *Thiocystis*
- b. *Thiocapsa*
- c. *Thiosphaera*
- d. *Thiosphaerion*
- e. *Thiosarcina*

Subfamily 2b. *Lamprocystaceae*

- Genus a. *Lamprocystis*

Subfamily 3c. *Thiopediaceae*

- Genus a. *Thiopedia*
- b. *Thioderma*

Subfamily 4d. *Amoebobacteriaceae*

- Genus a. *Amoebobacter*
- b. *Thiothece*
- c. *Thiodictyon*
- d. *Thiopolycoccus*

Subfamily 5e. *Chromatiaceae*

- Genus a. *Chromatium*
- b. *Rhabdochromatium*
- c. *Thiorhodospirillum*

Subfamily 6f. *Rhodocapsaceae*

- Genus a. *Rhodocapsa*
- b. *Rhodothece*

Family 2. *Athiorhodaceae*Subfamily 1a. *Rhodocystaceae*

- Genus a. *Rhodocystis*
- b. *Rhodonostoc*
- c. *Rhodococcus*
- d. *Rhodobacterium*
- e. *Rhodobacillus*
- f. *Rhodovibrio*
- g. *Rhodospirillum*

Order III. *Thiobacteria*Family 1. *Beggiatoaceae*

- Genus a. *Thiothrix*
- b. *Beggiatoa*
- c. *Thioploca*

Family 2. *Thiobacteriaceae*

- Genus a. *Thiophysa*
- b. *Thiobacterium*
- c. *Thiobacillus*
- d. *Thiovibrio*
- e. *Thiospirillum*
- f. *Thiosphaerella*
- g. *Thiovulum*
- h. *Achromatium*

Order IV. *Phycobacteria*

- Genus a *Leptothrix*
- b. *Clonothrix*
- c. *Cladothrix*
- d. *Crenothrix*
- e. *Phragmidiothrix*

Appendix Genera *Gallionella*, *Spirophyllum*, *Nodofolium*Order V. *Mycobacteria*Family 1. *Mycobacteriaceae*

- Genus a *Corynebacterium*
- b *Mycobacterium*

Family 2. *Actinomycetaceae*

- Genus a. *Actinomyces*
- b. *Actinococcus*

Order VI. *Myxobacteria*Family 1. *Myxobacteriaceae*

- Genus a. *Myxococcus*
- b. *Chondromyces*
- c *Polyangium*

Lehmann and Neumann (Bakt Diag., 2 vols, 7th ed, Munchen, 1926-27; Breed, Eng. trans., New York, 1931) developed their first simple and much used outline classification, drawn up in 1896, in later editions of their Determinative Bacteriology. The 1927 Lehmann and Neumann outline is as follows:

Class I. *Schizomycetes*Order I *Schizomycetales*Family 1. *Coccaceae*

- Genus a *Streptococcus*
- b. *Sarcina*
- c. *Micrococcus*
- Sub-genus a *Diplococcus*
- b (Gram-positive group)

Family 2. *Bacteriaceae*Genus a. *Bacterium*

- Sub-genus a *Nitrosomonas*
- b *Nitrobacter*
- c. *Rhizobium*
- d *Haemophilus*
- e *Brucella*
- f. *Pasteurella*
- g (Glanders and dysentery group)
- h. (Photogenic group)
- i (Aerogenes group)
- j. *Encapsulatus*
- k. (Typhoid group)\*
- l *Salmonella*
- m. (Coli group)\*

\* In a footnote under these groups, the authors refer to the names given by Castellani and Chalmers.

- n. *Acetobacterium*
- o. (Cloacae group)
- p. (Red chromogens)
- q. (Blue and violet chromogens)
- r. *Pseudomonas*
- s. *Proteus*
- App. *Erysipelothrix*
- Genus b. *Fusobacterium*
- c. *Plocamobacterium*
- Family 3. *Desmobacteriaceae*
- Genus a. *Beggiatoa*
- b. *Leptothrix*
- Sub-genus a. *Leptothrix*
- b. *Chlamydothrix*
- Genus c. *Crenothrix*
- d. *Cladothrix*
- e. *Thiothrix*
- Family 4. *Spirillaceae*
- Genus a. *Vibrio*
- b. *Spirillum*
- Family 5. *Spirochaetaceae*
- Genus a. *Spirochaeta*
- Family 6. *Bacillaceae*
- Genus a. *Bacillus*
- Sub-genus a. (Aerobic group)
- b. (Anaerobic group)
- Order II. *Actinomycetales*
- Family 1. *Proactinomycetaceae*
- Genus a. *Corynebacterium*
- b. *Mycobacterium*
- Family 2. *Actinomycetaceae*
- Genus a. *Actinomyces*

The generic term *Bacterium* is retained in this outline to cover those groups of the true bacteria that are Gram-negative, non-spore-forming, motile and non-motile rods. Lehmann and Neumann recognize 20 sub-groups in this genus, many of which correspond with the genera recognized in the MANUAL. In an effort to develop a rational nomenclature the term *Acetobacterium* (occurs first in review by Ludwig, Cent. f. Bakt., II Abt., 4, 1898, 870) is used in place of *Acetobacter*, *Plocamobacterium* (Loewi, Wien. klin. Wchnschr., 33, 1920, 730) in place of *Lactobacillus*, and *Fusobacterium* (Knorr, Cent. f. Bakt., I Abt., Orig., 89, 1922, 4) in place of *Fusiformis* without regard to priority. *Encapsulatus* Castellani and Chalmers (Manual Tropical Med., 3rd ed., 1919, 934) is used in place of *Klebsiella* Trevisan (Atti Accad. Fis.-Med.-Stat. Milano, Ser. 4, 3, 1885, 107).

Janke (Cent. f. Bakt., II Abt., 66, 1926, 481) reprints the classification developed in the first edition of the present MANUAL and compares it with that proposed by Orla-Jensen and Enderlein.

The second complete outline drawn up by Janke (Oesterr. Bot. Zeitschr., 78, 1929, 108) is similar to the classification employed by Lehmann and Neumann (Bakt. Diag., 2 vols., 7th ed., Munchen, 1926-27). He follows Enderlein in placing *Azotobacter* in close association with the spore-forming rods. No new generic terms are suggested. His sub-groups of the genus *Bacterium* are even more closely similar to the genera used in the present edition of the MANUAL than are the sub-groups of Lehmann and Neumann.

Family 1. *Coccaceae*

Genus a. *Micrococcus*

b. *Neisseria*

c. *Streptococcus*

Divided into 4 groups.

d. *Sarcina*

Divided into 2 groups.

Family 2. *Bacillaceae*

Genus a. *Bacillus*

Divided into 16 groups

b. *Azotobacter*

Family 3. *Bacteriaceae*

Genus a. *Bacterium*

Divided into 27 groups

b. *Fusiformis*

Family 4. *Corynebacteriaceae*

Genus a. *Mycobacterium*

b. *Corynebacterium*

c. *Actinomyces*

Family 5. *Spirillaceae*

Genus a. *Microspira*

Divided into 2 groups.

b. *Spirillum*

Divided into 2 groups.

Family 6. *Spirochaetaceae*

Genus a. *Spirochaeta*

b. *Borrelia*

c. *Treponema*

d. *Cristispira*

e. *Saprospira*

f. *Leptospira*

Family 7. *Desmobacteriaceae*

Genus a. *Beggiatoa*

b. *Thioploca*

c. *Thiothrix*

d. *Leptotrichia*

e. *Crenothrix*

f. *Sphaerotilus*

g. *Clonothrix*

h. *Leptothrix*

i. *Phragmidiothrix*

Family 8 *Myzobacteriaceae*Genus a. *Myzococcus*b. *Polyangium*c. *Chondromyces*

Pribram (Jour. Bact., 18, 1929, 361) has rearranged some groups and combined others (e.g., *Rhizobium*, *Diplococcus*, *Leuconostoc*, *Serratia*, *Flavobacterium*, *Chromobacterium*, *Achromobacter*, *Cellulomonas*) recognized in the first edition of the MANUAL with little change in the nomenclature except among the anaerobic non-spore-forming rods and among the spore-forming rods. Unfortunately, he has sometimes used family and species names as generic names, thus in the latter case introducing adjectives and adjectival terms as substantives. New generic terms suggested are: *Dialisterea*, *Bacterioidea*, *Centrosporus*, *Fusibacillus*, *Pseudobacillus*, *Megatherium*, *Flexus*, *Anthrax*, *Botulinus*, *Chauwoea*, *Botulinea*, *Putrificus*, *Welchia*, *Phleobacterium*, *Distasoa*, *Tissieria*, and *Actinoidomyces*. *Astasia* as it appears in this outline does not appear to be the same as *Astasia* Meyer (Flora, 84, 1897, 185). *Aerobacillus* is not synonymous with *Aerobacillus* Donker (Inaug. Diss., Delft, 1926). *Sideromonas* is accepted from Cholodny (Ber. Deutsch. Bot. Ges., 40, 1922, 326).

Pribram's complete outline follows:

Class *Schizomycetes*Subclass A. *Protozoobacteria*Order I. *Spirochaetales*Family 1. *Spirochaetaceae*Genus a. *Spirochaeta*b. *Treponema*c. *Spironema*Family 2. *Cristispiraceae*Genus a. *Saprospira*b. *Cristispira*c. *Leptospira*Subclass B. *Eubacteria*Order I. *Protobacteriales*Family 1. *Nitrobacteriaceae*Related to *Pseudomonas*Tribe A. *Hydrogenomonadae*Genus a. *Hydrogenomonas*b. *Methanomonas*c. *Carboxydomonas*Tribe B. *Nitrobactereae*Genus a. *Nitrosomonas*b. *Nitrobacter*Family 2. *Thiobacillaceae*Tribe A. *Thiobacilleae*Genus a. *Thiobacillus*

Order II. *Metabacteriales*Family 1. *Pseudomonadaceae*Tribe A. *Spirilleae*Genus a. *Spirillum*Tribe B. *Vibrionaeae*Genus a. *Vibrio*Tribe C. *Pseudomonadeae*Genus a. *Pseudomonas*b. *Azotobacter*Connects with *Polyangiaceae* and *Nitrobacteriaceae*Family 2. *Bacteriaceae*Tribe A. *Aerobactereae*Genus a. *Aerolacter*b. *Escherichia*c. *Salmonella*d. *Eberthella*e. *Proteus*Tribe B. *Pasteurelleae*Genus a. *Alcaligenes*b. *Pasteurella*Connects with *Pfeifferella*c. *Hemophilus*Connects with *Dialister*Family 3. *Micrococcaceae*Tribe A. *Streptococceae*Genus a. *Neisseria*b. *Streptococcus*Tribe B. *Micrococceae*Genus a. *Micrococcus*b. *Staphylococcus*c. *Sarcina*Connects with *Algo bacteria*Subclass C. *Mycobacteria*Order I. *Bacteriomycetales*Family 1. *Leptotrichaceae*Tribe A. *Acetobactereae*Genus a. *Acetobacter*Connects with *Salmonella* and *Tissieria*Tribe B. *Leptotrichaeae*Genus a. *Kurtzia*b. *Lactobacillus*Connects with *Corynebacterium*c. *Leptotrichia*Connects with *Erysipelothrix*Family 2. *Bacteroidaceae*Tribe A. *Dialisterae*Genus a. ———— Type species *Dialistera variegata*Connects with *Distosia*b. ———— Type species *Dialistera variabilis*c. *Dialister*

Connects with *Hemophilus*

Tribe B. *Bacteroidae*

Genus a. ——— Type species *Bacteroides multiformis*

b. *Bacteroides*

Connects with *Tissieria*

c. ——— Type species *Bacteroides fusiformis*

Order II. *Bacillomycetales*

Family 1. *Bacillaceae*

Sub-family 1a. *Aerobacilloideae*

Tribe A. *Aerobacilleae*

Sub-tribe A1. *Centrosporineae*

Genus a. *Centrosporus*

b. *Fusibacillus*

Sub-tribe A2. *Aerobacillineae*

Genus a. *Aerobacillus*

Tribe B. *Pseudobacilleae*

Genus a. *Pseudobacillus*

Sub-family 1b. *Bacilloideae*

Tribe A. *Bacilleae*

Sub-tribe A1. *Bacillineae*

Genus a. *Bacillus*

b. *Megatherium*

Sub-tribe A2. *Astasineae*

Genus a. *Astasia*

b. *Flexus*

Tribe B. *Anthraceae*

Genus a. *Anthrax*

Family 2. *Clostridiaceae*

Sub-family 2a. *Botulinoideae*

Tribe A. *Botulineae*

Genus a. *Botulinus*

b. *Chauvoea*

c. ——— Type species *Botulina saccharolytica*

d. ——— Type species *Botulina butyrica*

Tribe B. *Putrifcae*

Genus a. *Putrificus*

Sub-family 2b. *Clostridioideae*

Tribe A. *Welchieae*

Genus a. *Welchia*

Tribe B. *Clostridiace*

Genus a. *Clostridium*

Order III. *Actinomycetales*

Family 1. *Mycobacteriaceae*

Tribe A. *Actinobacilleae*

Genus a. *Pfeifferella*

Connects with *Pasteurella*

b. *Actinobacillus*

c. *Corynebacterium*

d. *Erysipelothrix*

Connects with *Leptotrichia*

Tribe B. *Mycobacteriae*Genus a. *Phleobacterium*b. *Mycobacterium*Tribe C. *Tissieriae*Genus a. *Distasoa*b. *Tissieria*Connects with *Bacteroides*, *Corynebacterium* and *Acetobacter*Family 2. *Actinomycetaceae*Tribe A. *Actinoidomycetaceae*Genus a. *Actinoidomyces*Tribe B. *Actinomycetaceae*Genus a. *Actinomyces*Subclass D. *Algobacteria*Order I. *Desmobacteriales*Family 1. *Sphaerotilaceae*Genus a. *Sphaerotilus*Order II. *Siderobacteriales*Family 1. *Chlamydotrichaceae*Tribe A. *Chlamydotricheae*Genus a. *Leptothrix*b. *Crenothrix*Family 2. *Siderocapsaceae*Genus a. *Didymohelix*b. *Siderocapsa*c. *Sideromonas*Order III. *Thiobacteriales*Family 1. *Rhodobacteriaceae*Sub-family 1a. *Chromatoideae*Tribe A. *Thiocapsee*Genus a. *Thiocystis*b. *Thiosphaera*c. *Thiosphaerion*d. *Thiocapsa*e. *Thiosarcina*f. *Lamprocystis*Tribe B. *Thiopediace*Genus a. *Lampropedia*b. *Thioderma*Tribe C. *Amoebobacteriae*Genus a. *Amoebobacter*b. *Thiodietyon*c. *Thiothece*d. *Thiopolycoecus*Tribe D. *Chromatieae*Genus a. *Chromatium*b. *Rhabdomonas*c. *Thiospirillum*d. *Rhodocapsa*e. *Rhodotherce*

Sub-family 1b. *Rhodobacteroideae*Tribe A. *Rhodobacteriaceae*Genus a. *Rhodobacterium*b. *Rhodobacillus*c. *Rhodovibrio*d. *Rhodospirillum*e. *Rhodospiracra*Tribe B. *Rhodocystaceae*Genus a. *Rhodocystis*b. *Rhodonostoc*Connects with *Leuconostoc*Family 2 *Beggiatoaceae*Genus a. *Thiothrix*b. *Beggiatoa*c. *Thioploca*Family 3. *Achromatiaceae*Genus a. *Achromatium*b. *Thiophysa*c. *Thiospira*d. *Hillhousia*Order IV. *Myxobacteriales*Family 1. *Polyangiaceae*Genus a. *Chondromyces*b. *Polyangium*Family 2. *Myxococcaceae*Genus a. *Myxococcus*

Later Pribram (Klassifikation der Schizomyceten (Bakterien), Leipzig and Wien, 1933, 143 pp.) developed this classification into a suggestive outline based on his experience in caring for the cultures of the Kral Collection. His most interesting contribution is the separation of the class of *Schizomycetes* into three subclasses which are based on differences in fundamental biological and nutritional relationships. The fourth sub-class of his earlier outline (the *Protozoobacteria* with its single order *Spirochaetales*) is omitted from this outline. The first class, *Algobacteria*, includes the bacteria that are primarily free living in water, usually motile with polar flagellation and live on easily soluble foodstuffs. They are frequently surrounded by insoluble secretions such as capsules, sheaths, etc., and form insoluble products in their protoplasm, such as calcium, sulfur and iron compounds, and pigments. The class *Eubacteria* includes those bacteria whose normal habitat is the animal body or complex waste products of plant or animal origin. Because of adaptation to environment, these organisms are motile or non-motile and can utilize compounds of complex molecular structure. The third sub-class, *Mycobacteria*, is adapted to life in soil, and shows a distinct tendency to differentiation in morphology and spore formation.

Internationally accepted rules of nomenclature are generally followed, and the generic terms proposed in his earlier outline that were not formed

in accordance with recommended practices are discarded. He has revived *Ulvina* Kützing, 1837 (status explained by Buchanan, General Systematic Bacteriology, 1925, p. 518) in place of *Acetobacter* Beijerinck and accepted *Plocamobacterium* (Loewi, Wien klin. Wchschr., 33, 1920, 730) in place of *Lactobacillus* Beijerinck, 1901. Among the spore-forming rods, he has accepted *Bactrillum* Fischer and *Welchillus* Heller, 1921. *Malleomyces* Hallier (Bot. Ztg., 24, 1866, 383) is used for the glanders bacillus. *Anthraccillus* is apparently new.

The new outline has the following form:

- Class *Schizomycetes*
  - Subclass A. *Algobacteria*
    - Order 1. *Micrococcales*
      - Family 1 *Micrococcaceae*
        - Genus a. *Micrococcus*
        - b. *Rhodococcus*
        - c. *Rhodocapsa*
        - d. *Thiocapsa*
        - e. *Thiosphaera*
        - f. *Thiosphaerion*
        - g. *Thiocystis*
        - h. *Lamprocystis*
        - i. *Sarcina*
        - j. *Thiosarcina*
      - Family 2 *Pediococcaceae*
        - Genus a. *Pediococcus*
        - b. *Lampropedia*
        - c. *Thiothece*
        - d. *Thioplycoccus*
        - e. *Thioderma*
        - f. *Amoebomonas*
        - g. *Rhodotheca*
        - h. *Rhodonostoc*
        - i. *Thiophysa*
    - Order 2 *Pseudomonadales*
      - Family 1. *Pseudomonadaceae*
        - Genus a. *Pseudomonas*
        - b. *Rhodobacillus*
        - c. *Chromatium*
        - d. *Nitrosomonas*
        - e. *Vibrio*
        - f. *Rhodovibrio*
        - g. *Myxococcus*
        - h. *Spirillum*
        - i. *Rhodospirillum*
        - j. *Thiospira*
        - k. *Thiospirillum*
      - Family 2. *Serratiaaceae*
        - Genus a. *Serratia*
        - b. *Hillhousta*

Family 3. *Nitrobacteriaceae*

- Genus a. *Nitrobacter*
- b. *Rhodobacterium*
- c. *Rhodocystis*
- d. *Didymoheliz*
- e. *Sideromonas*
- f. *Siderocapsa*
- g. *Chondromyces*
- h. *Polyangium*
- i. *Amoebobacter*
- j. *Thiodictyon*

Family 4. *Azotobacteriaceae*

- Genus a. *Rhizobium*
- b. *Azotobacter*

Order 3. *Leptotrichales*Family 1. *Leptotrichaceae*

- Genus a. *Leptothrix*
- b. *Sphaerotilus*
- c. *Crenothrix*

Family 2. *Clonothrichaceae*

- Genus a. *Clonothrix*

Order 4. *Rhabdomonadales*Family 1. *Rhabdomonadaceae*

- Genus a. *Beggiatoa*
- b. *Rhabdomonas*
- c. *Thioploca*
- d. *Thiothrix*

Family 2. *Spirochaetaceae*

- Genus a. *Spirochaeta*
- b. *Treponema*
- c. *Leptospira*
- d. *Cristispira*
- e. *Saprosira*

Subclass B. *Eubacteria*Order 1. *Aerobacteriales*Family 1. *Aerobacteriaceae*

- Genus a. *Aerobacter*
- b. *Escherichia*
- c. *Salmonella*
- d. *Eberthella*
- e. *Shigella*

Family 2. *Pasteurellaceae*

- Genus a. *Pasteurella*
- b. *Brucella*
- c. *Haemophilus*
- d. *Neisseria*

Order 2. *Plocamobacteriales*Family 1. *Streptococcaceae*

- Genus a. *Streptococcus*

Family 2. *Ulvinaceae*

- Genus a. *Proteus*
- b. *Kurthia*

- c. *Ulvina*
- d. *Plocamobacterium*
- e. *Leptotrichia*
- Family 3. *Bacteroidaceae*
  - Genus a. *Dialister*
  - b. *Aerobacteroides*
  - c. *Bacteroides*
  - d. *Fusobacterium*
- Subclass C. *Mycobacteriæ*
  - Order 1. *Bacillales*
    - Family 1. *Bacillaceae*
      - Genus a. *Bactrillum*
      - b. *Aerobacillus*
      - c. *Bacillus*
      - d. *Anthraxillus*
    - Family 2. *Clostridiaceae*
      - Genus a. *Clostridium*
      - b. *Welchillus*
  - Order 2. *Mycobacteriales*
    - Family 1. *Mycobacteriaceae*
      - Genus a. *Malleomyces*
      - b. *Actinobacillus*
      - c. *Corynebacterium*
      - d. *Erysipelothrix*
      - e. *Mycobacterium*
      - f. *Distasoa*
      - g. *Tissieria*
    - Family 2. *Actinomycetaceae*
      - Genus a. *Actinomycoides*
      - b. *Actinomycetes*

Janke (Cent. f. Bakt., II Abt., 80, 1930, 481) reprints the earlier outline prepared by Pribram (1929) and, after commenting on Lehmann and Neumann's (1927) outline, proposes an outline which is slightly modified from his own previous (1929) outline. Two new subgeneric terms are used, *Anaerobacillus* and *Eubacterium*. The sub-genus *Acrobacillus* is apparently not the same as *Acrobacillus* Donker (Inaug. Diss., Delft, 1926), nor as *Acrobacillus* Pribram (Jour. Bact., 18, 1929, 361).

- Family I. *Micrococcaceae*
  - Genus 1. *Micrococcus*
    - Divided into 2 sections.
    - 2. *Neisseria*
    - 3. *Streptococcus*
      - Divided into 4 sections.
    - 4. *Sarcina*
      - Divided into 2 sections.
- Family II. *Bacillaceae*
  - Genus 1. *Bacillus*
    - Sub-genus a. *Anaerobacillus* or better *Clostridium*
      - Divided into 6 sections.

- b. *Aerobacillus* or better *Eubacillus*  
Divided into 10 sections.
- Family III. *Bacteriaceae*
  - Genus 1. *Bacterium*
    - Sub-genus a. *Pseudomonas*  
Divided into 6 sections.
    - b. *Eubacterium*  
Divided into 11 sections.
    - c. *Trichobacterium*  
Divided into 6 sections.
  - Genus 2. *Fusiformis*
- Family IV. *Corynebacteriaceae*
  - Genus 1. *Mycobacterium*
    - 2. *Pfeifferella*
    - 3. *Erysipelothrix*
    - 4. *Corynebacterium*
    - 5. *Actinomyces*
- Family V. *Spirillaceae*
  - Genus 1. *Microspira* or *Vibrio*
    - Sub-genus a. *Microspira*
    - b. *Spirosoma*
  - Genus 2. *Spirillum*
    - Sub-genus a. *Spirella*
    - b. *Dicrospirillum*
- Family VI. *Spirochaetaceae*
  - Genus 1. *Spirochaeta*
    - 2. *Cacospira*
    - 3. *Entomospira*
    - 4. *Treponema*
    - 5. *Cristispira*
    - 6. *Saprospira*
    - 7. *Leptospira*
- Family VII. *Desmobacteriaceae*  
As in 1929 outline.
- Family VIII. *Myzobacteriaceae*  
As in 1929 outline.

Kluyver and Van Niel (Cent. f. Bakt., II Abt., 94, 1936, 369) have developed an outline classification in which they indicate four lines of development from the simplest form of cell that is existent and conceivable, the sphere. They assign family rank to each of these four groups of bacteria, placing the lophotrichous (and related non-motile) rod-shaped bacteria first (*Pseudomonadaceae*). This is followed by the family of spherical bacteria (*Micrococcaceae*) and the family of permanently non-motile, rod-shaped bacteria (*Mycobacteriaceae*). The final family includes the peritrichous (and related non-motile) rod-shaped bacteria, the *Bacteriaceae*. These are grouped in the tribes of each family in accordance with their fundamental metabolism as photo-autotrophic, photo-heterotrophic, chemo-autotrophic and chemo-heterotrophic. Their outline follows:

Family A. *Pseudomonadaceae*I. Tribe *Spirilleae*

- Genus 1. *Thiospirillum*  
 2. *Phaeospirillum*  
 3. *Rhodospirillum*  
 4. *Sulfospirillum*  
 5. *Spirillum*

II. Tribe *Vibrionaeae*

- Genus 1. *Chromatium*  
 2. *Rhodovibrio*  
 3. *Didymohelix*  
 4. *Vibrio*  
 5. *Desulfovibrio*

III. Tribe *Pseudomonadeae*

- Genus 1. *Thiothece*  
 2. *Phaeomonas*  
 3. *Rhodomonas*  
 4. *Sulfomonas*  
 5. *Sideromonas*  
 6. *Nitrosomonas*  
 7. *Nitrobacter*  
 8. *Acetobacter*  
 9. *Pseudomonas*  
 10. *Rhizobium*  
 11. *Azotobacter*  
 12. *Listerella*  
 13. *Aeromonas*  
 14. *Zymomonas*  
 15. *Methanobacterium*

Family B. *Micrococcaceae*IV. Tribe *Micrococceae*

- Genus 1. *Chlorobium*  
 2. *Thiopolycoccus*  
 3. *Rhodococcus*  
 4. *Achromatium*  
 5. *Siderocapsa*  
 6. *Nitrosococcus*  
 7. *Neisseria*  
 8. *Micrococcus*  
 9. *Veillonella*  
 10. *Peptococcus*  
 11. *Methanococcus*

V. Tribe *Sarcineae*

- Genus 1. *Thiopredia*  
 2. *Thioarscina*  
 3. *Gaffkya*  
 4. *Sarcina*  
 5. *Zymosarcina*  
 6. *Butyrissarcina*  
 7. *Melanosarcina*

- VI. Tribe *Sporosarcinae*
  - Genus 1. *Sporosarcina*
- VII. Tribe *Streptococcae*
  - Genus 1. *Peptostreptococcus*
  - 2. *Streptococcus*
  - 3. *Betacoccus*
- Family C. *Mycobacteriaceae*
- VIII. Tribe *Corynebacteriaceae*
  - Genus 1. *Corynebacterium*
  - 2. *Fusiformis*
  - 3. *Propionibacterium*
  - 4. *Streptobacterium*
  - 5. *Betabacterium*
- IX. Tribe *Mycobacteriaceae*
  - Genus 1. *Mycobacterium*
  - 2. *Thermobacterium*
- Family D. *Bacteriaceae*
- X. Tribe *Bacteriaceae*
  - Genus 1. *Kurthia*
  - 2. *Alcaligenes*
  - 3. *Bacterium*
  - 4. *Aerobacter*
- XI. Tribe *Bacillaceae*
  - Genus 1. *Bacillus*
  - 2. *Aerobacillus*
  - 3. *Zymobacillus*
  - 4. *Clostridium*
  - 5. *Peptoclostridium*

Some old names are displaced by new descriptive terms: *Phacospirillum*, *Sulfospirillum*, *Desulfovibrio*, *Phacomonas*, *Acromonas*, *Zymomonas*, *Methanobacterium*, *Methanococcus*, *Methanosarcina*, *Butyrisarcina*, *Peptococcus*, *Peptostreptococcus*, *Zymobacillus*. *Rhodomonas* is not used in the same sense as *Rhodomonas* Orla-Jensen (Cent. f. Bakt., II Abt., 22, 1909, 331 and 334), the latter being a synonym of *Chromatium* Perty (Zur Kenntniss kleinster Lebensformen, 1852). *Sulfomonas* is indicated as new and as a synonym of *Thiobacillus* Beijerinck (Cent. f. Bakt., II Abt., 11, 1904, 598) although the same term is used by Orla-Jensen (*loc. cit.*). Three new terms are accepted: *Chlorobium* Nadson (Bull. Jard. Bot. St. Petersburg, 6, 1906, 184), *Zymosarcina* Smit (Die Gärungssarcinen, Jena, 1930) and *Peptoclostridium* (Donker, Inaug. Diss., Delft, 1926).

Rahn (Cent. f. Bakt., II Abt., 96, 1937, 273) has reviewed the characters of the species of *Eubacteriales* included in the fourth edition of this MANUAL. He places 146 of the spore-forming species in a Sub-order A. *Endosporales* with a single family, and 536 of the species of non-spore-forming rods in a Sub-order B. *Asporales* in seven families. Unclassifiable species (total 224) are placed in a temporary eighth family *Bacteriaceae*. His outline follows:

Order Eubacteriales

Suborder A. Endosporales

Family I. Endosporaceae

- Genus 1. *Bacillus*
- 2. *Aerobacillus*
- 3. *Clostridium*

Suborder B. Asporales

Family I. Gramozidaceae

- Genus 1. *Micrococcus* (including *Staphylococcus*, *Gaffkya*, *Rhodococcus* and most of the species of *Sarcina*)

- 2. *Kurtkia*

Family II. Gramanoxidaceae

Tribe a. Streptococceae

- Genus 1. *Streptococcus* (including *Diplococcus*)
- 2. *Leuconostoc*
- 3. *Peptostreptococcus*

Tribe b. Lactobacilleae

- Genus 4. *Lactobacillus* (including part of *Bacteroides*)

- 5. *Propionibacterium*

Tribe c. Sarcineae

- Genus 6. *Zymosarcina*
- 7. *Butyrisarcina*
- 8. *Methanosarcina*

Family III. Neisseriaceae

- Genus 1. *Neisseria*
- 2. *Veillonella*

Family IV. Protobacteriaceae

Tribe a. Protobacterieae

- Genus 1. *Carboxydomonas*
- 2. *Methanomonas*

Tribe b. Nitrobacterieae

- Genus 1. *Nitrosomonas*
- 2. *Nitrobacter*
- 3. *Nitrosococcus*

Family V. Enterobacteriaceae

- Genus 1. *Enterobacter* (including *Escherichia*, *Salmonella*, *Aerobacter*, *Klebsiella*, *Proteus*, *Erwinia*, *Eberthella*, *Shigella*, and parts of *Serratia*, *Pseudomonas*, *Flavobacterium* and *Achromobacter*)

Family VI. Pseudomonadaceae

- Genus 1. *Pseudomonas* (includes *Phytomonas* and other lephotrichous types only)

- 2. *Vibrio*
- 3. *Spirillum*
- 4. *Acetobacter*
- 5. *Azotobacter*
- 6. *Rhizobium*

Family VII. *Parvobacteriaceae*Genus 1. *Brucella*2. *Pasteurella*3. *Hemophilus* (including *Dialister*)Family VIII. *Bacteriaceae*

Unclassifiable genera including *Alcaligenes* and *Protaminobacter*; some species from each of the following genera, *Achromobacter*, *Chromobacterium*, *Cellulomonas*, *Bacteroides*, *Flavobacterium*, *Phytomonas*, *Pseudomonas*, *Serratia*; and three species from the Family *Nitrobacteriaceae*.

One of the generic terms used in this outline is new, i.e., *Enterobacter*. Two other generic terms, *Fluorescens* and *Erythrobacterium*, are proposed incidentally (p. 284). The first includes the peritrichous forms included in the MANUAL under *Pseudomonas* and the second includes those red, non-spore-forming rods that are not included in *Serratia*. In another footnote (p. 281) a substitute, *Virgula*, is suggested for *Enterobacter*. Emphasis is placed on sporulation, Gram stain, and oxygen demand as the most important characters aside from cell form and flagellation.

Prévot, as an outgrowth of his studies on anaerobes with Weinberg (Weinberg, Nativelle and Prévot, *Les microbes anaérobies*, 1937, 1186 pp., Paris), has written a series of papers in which he has developed a classification of anaerobic bacteria (Ann. Sci. Nat., 10 Sér., 15, 1933, 23-260; Ann. Inst. Past., 60, 1938, 285-307; 61, 1938, 72-91; 64, 1940, 117-125). The conclusions reached in these studies are summarized in his *Manual de Classification et de Détermination des Bactéries Anaérobies*, Monographie de l'Institut Pasteur, Paris, 1940, 223 pp. He regards the bacteria as comprising a kingdom, *Schizomycetes*, intermediate between the animal and plant kingdoms and notes the presence of strict anaerobes in at least three of the seven orders recognized in the 5th edition of the MANUAL. These orders he regards as classes. The genus *Bacteroides* Castellani and Chalmers (Manual of Trop. Med., 3rd ed., 1919, 959) type species, *Bacteroides fragilis*, is dropped (Ann. Inst. Past., 60, 1938, 288), and several new terms are proposed for the organisms included by Castellani and Chalmers and later investigators in the genus. Among the new generic names is *Ristella* which is based on *Ristella fragilis*, the species used by Castellani and Chalmers as the type species for *Bacteroides*.

The complete outline classification developed by Prévot in his Monograph (*loc. cit.*, p. 17) is given below:

Kingdom. *Schizomycetes* Nägeli

Class I. *Eubacteriales*

Sub-Class I. Non sporogenous *Eubacteriales*

Order I. *Micrococcales*

Family I. *Neisseriaceae*Tribe I *Neisserieae*Genus a *Neisseria*Tribe 2 *Veillonelleae*Genus a *Veillonella*Family 2 *Micrococcaceae*Tribe 1 *Streptococcaceae*Genus a *Diplococcus*b *Streptococcus*Tribe 2 *Staphylococcaceae*Genus a. *Gaffkia*b. *Staphylococcus*Tribe 3 *Micrococcaceae*Genus a *Sarcina*b *Micrococcus*Order II. *Bacteriales*Family 1 *Ristellaceae*Genus a *Ristella*b *Pasteurella*c. *Dialister*d. *Zuberella*e. *Capsularis*Family 2. *Bacteriaceae*Genus a *Eubacterium*b *Catenobacterium*c. *Ramibacterium*d *Cillobacterium*Order III. *Spirillales*Family 1 *Vibrionaceae*Genus a. *Vibrio*Sub-class II *Sporogenous Eubacteriales*Order I *Clostridiales*Family 1 *Endosporaceae*Genus a *Endosporus*b *Paraplectrum*Family 2 *Clostridiaceae*Genus a *Inflabilis*b. *Welchia*c *Clostridium*Order II *Plectridiales*Family 1 *Terminosporaceae*Genus a *Terminosporus*b. *Caduceus*Family 2 *Plectridiaceae*Genus a. *Plectridium*b *Aeuformis*Order III. *Sporovibrionales*Family 1. *Sporovibrionaceae*Genus a *Sporovibrio*

Class II. *Actinomycetales*Family 1. *Spherophoraceae*Genus a. *Spherophorus*b. *Spherocillus*c. *Fusiformis*d. *Fusocillus*e. *Leptotrichia*Family 2. *Actinomycetaceae*Genus a. *Actinobacterium*b. *Bifidibacterium*c. *Corynebacterium*Class III. *Spirochetales*Family 1. *Spirochaetaceae*Genus a. *Treponema*b. *Borrelia*

In this outline, there are minor modifications in the names and in endings given to the orders and tribes as compared with those given in his preliminary papers. In the Order *Micrococcales*, *Leuconostoc* has been dropped as a genus of the tribe *Streptococceae* and *Rhodococcus* has been dropped as a genus of the Tribe *Staphylococceae*. *Veillonella* proposed by Prévot as a new genus in 1933 (*loc. cit.*, p. 70) is included as a genus in the Family *Neisseriaceae*. The spelling of *Gaffkya* is changed to *Gaffkia*. In the first of Prévot's papers published in 1938 (*loc. cit.*), he proposes the following new genera in the Order *Bacteriales*: *Ristella*, *Zuberella*, *Capsularis*, *Eubacterium*, *Catenabacterium*, *Ramibacterium* and *Cillobacterium*. In the same paper he also proposes the following new genera in the Order *Actinomycetales*: *Spherophorus*, *Spherocillus*, *Fusocillus*, *Pseudoleptothrix* (withdrawn in 1940 in favor of *Leptotrichia* Trevisan). He also accepts one genus *Actinobacterium* (Haas, *Cent. f. Bakt.*, I Abt., Orig., 40, 1906, 180) not previously mentioned in this discussion. With the single change noted (*Pseudoleptothrix* to *Leptotrichia*), the outlines of the genera in the orders *Bacteriales* and *Actinomycetales* remains in the 1940 outline as it was given in 1938.

In the outline given in Prévot's Monograph (*loc. cit.*, p. 17) one change is made in the generic terms recognized in the Order *Clostridiales* from those recognized in his second paper published in 1938. The genus name *Palmula* proposed in 1938, having been found to be invalid because of prior use for a genus of *Protozoa*, is changed to *Acuiformis*. Other generic names which appeared for the first time in the 1938 outline are *Endosporus*, *Inflabilis*, *Terminosporus* and *Caduceus*. *Welchia* proposed by Prévot in 1933 (*loc. cit.*, p. 44) was previously proposed by Pribram (*Jour. Bact.*, 18, 1929, 374) for the same group of anaerobic spore-forming rods. A third order, *Sporovibrionales*, is proposed by Prévot in his Monograph (*loc. cit.*, p. 15) to include the family *Sporovibrionaceae* (*Ann. Inst. Past.*, 64, 1940,

119). This order and family include a single genus *Sporovibrio* Starkey (Arch. f. Microb., 9, 1938, 300) syn. *Desulfovibrio* Kluver and Van Niel (Cent. f. Bakt., II Abt., 94, 1936, 389). Two genera (*Treponema* and *Borrelia*) of *Spirochaetales* are listed by Prévot in his Monograph (*loc. cit.*, p. 16) as including anaerobic species.

Stanier and Van Niel (Jour. Bact., 42, 1941, 437-466) have proposed a rearrangement of the classification outline as indicated below:

Kingdom *Monera*

Division I *Myxophyta* (Blue-green algae)

Division II *Schizomycetae* (Bacteria)

Class I *Eubacteriae*

Order I *Rhodobacteriales*

Order II *Eubacteriales*

Order III *Actinomycetales*

Class II *Myxobacteriae*

Order I *Myxobacteriales*

Class III *Spirochaetae*

Order I *Spirochaetales*

Appendix to Division *Schizomycetae*

Group I Includes two families, *Leptotrichaceae* and *Crenothri-*  
*caceae*

Group II *Achromatiaceae*

Group III *Pasteuriaceae* (Includes three genera, *Pasteuria*, *Hypho-*  
*microbium* and *Blastocaulis*)

The genera *Mycobacterium*, *Corynebacterium*, *Erysipelothrix*, *Leptotrichia*, *Nevskia*, *Gallionella*, *Caulobacter*, *Thiospira*, *Siderocapsa* and *Sideromonas* are placed in *Eubacteriales*. Two genera not previously discussed in this review whose relationships to other bacteria have recently been clarified are *Sporocytophaga* Stanier (Jour. Bact., 40, 1940, 629) and *Cytophaga* Winogradsky (Ann Inst. Past., 43, 1929, 578).

This rearrangement has been carried out by including the organisms placed in the Order *Caulobacteriales* Henrici and Johnson (Jour. Bact., 30, 1935, 61-93) in the Order *Eubacteriales* (Buchanan, Jour. Bact., 2, 1917, 162). The genera of the Order *Chlamydoacteriales* Buchanan (*loc. cit.*) are transferred to an appendix or are dropped (*Clonothrix*) as belonging to the blue-green algae. Three of the remaining five orders are raised to the rank of classes, one of which (*Eubacteriae*) includes three orders *Rhodobacteriales* (Pringsheim, Lotos, 71, 1923, 351), *Eubacteriales* (Buchanan, *loc. cit.*) and *Actinomycetales* (Buchanan, *loc. cit.*). *Rhodobacteriales* includes the sulfur purple, the non-sulfur purple and the green bacteria, the colorless sulfur bacteria (*Beggiatoaceae*) being transferred to the *Myxophyta* with the change of the name of the Order from *Thiobacteriales* Buchanan (*loc. cit.*) to *Rhodobacteriales* Pringsheim (*loc. cit.*).

The outline classification below is proposed by the Editorial Board of the *MANUAL* for use in the present (6th) edition of the *MANUAL*. It is based on those developed by Bergey et al. in earlier editions. These, in turn, were based on the outline classifications developed by Buchanan (*Jour. Bact.*, 2, 1916, 591; 3, 1917, 155 E.; 5, 1918, 27 ff.) and Winslow et al. (*Jour. Bact.*, 5, 1920, 191).

Phylum *Schizophyta*

Class I. *Schizophyceae*

Class II. *Schizomycetes*

Order I. *Eubacteriales*

Sub-Order I. *Eubacteriineae* (includes *Corynebacteriaceae*)

Sub-Order II. *Corynebacteriineae*

Sub-Order III. *Rhodobacteriineae*

Order II. *Actinomycetales* (includes *Mycobacterium*, *Actinomyces*, and related genera)

Order III. *Chlamydobacteriales*

Family I. *Leptotrichaceae*

Family II. *Crenothrichaceae*

Family III. *Beggiatoaceae*

Appendix *Achromatiaceae*

Order IV. *Mycobacteriales*

Order V. *Spirerochaetales*

Supplement: Groups whose relationships are uncertain.

Group I. Order *Rickettsiales*. Group II. Order *Virales*. Group III.

Family *Borrelomycetaceae*.

In this, the arrangement of *Schizomycetes* as a class coordinate with *Schizophyceae*, both belonging to a phylum *Schizophyta* of the plant kingdom, is maintained as before. The number of orders is reduced from seven as given in the fifth edition of the *MANUAL* to five, through recognition of the fact that the rigid, unicellular, sometimes branching but never truly mycelial nor filamentous organisms belonging to three of the previously recognized orders are presumably more closely related to each other than they are to the organisms in the four remaining orders. The family *Corynebacteriaceae* has been transferred from the order *Actinomycetales* to *Eubacteriales*.

The colorless, filamentous, sulfur bacteria (*Beggiatoaceae*) have been placed in the order *Chlamydobacteriales* with the other filamentous bacteria that are clearly related to the blue-green algae. While this marks the greatest deviation from the outline previously used, and separates these colorless sulfur bacteria from the purple sulfur bacteria placed in *Rhodobacteriineae*, it is in accordance with the arrangement accepted by Lehmann and Neumann (*Bakt. Diag.*, 4 Aufl., 2, 1907, 598), Pringsheim (*Lotus*, 71, 1923, 307) and others. *Rhodobacteriineae* is also limited to the purple and green bacteria as suggested by Pringsheim (*loc. cit.*) and accepted by Kluyver and Van Niel (*loc. cit.*), by Stanier and Van Niel (*loc. cit.*) and others.

The *Rickettsiales* and *Borrelomycetaceae* are placed in a supplement as their relationships are still obscure. Several authors would place them near some of the organisms now placed in *Pasteurella* and *Haemophilus*. The viruses (*Virales*) whose nature and relationships are still more obscure are also placed in a supplemental group.

Although this outline maintains the simplicity that distinguished its predecessors, and provides places for all types of microorganisms thus far described that may properly be grouped under the fission fungi, it should not be regarded in any sense as final. An attempt has been made to express natural relationships, but these are so frequently obscure or unknown that in many places utilitarian considerations have prevailed. In some places, groups of known doubtful significance have been allowed to stand as they are out of a desire not to make unnecessary changes. It has appeared desirable to be conservative in making changes in the outline as used previously.

*Addenda:* After the above was in page proof, it was discovered that reference to the outline classification of Gieszczykiewicz (Bull. Acad. Polonaise d. Sci. et d. Lettres, Cl. Sci. Math. et Nat., Sér. B., 1939, 27 pp.) had inadvertently been omitted. This outline has some features like the outline that Lehmann and Neumann used in 1927 (see p. 17) and some like the outline used in the 4th ed. of the MANUAL.

The genus *Bacterium* is retained as in the Lehmann and Neumann outline for Gram-negative, non-spore-forming, peritrichous or polar flagellate rods. Twelve sub-genera are recognized and these bear subgeneric scientific names that are much the same as those used for genera in the 4th ed. of the MANUAL. A new subgeneric name *Enterobacterium* (see *Enterobacter* Rahn) is proposed to cover the genera *Escherichia*, *Aerobacter*, *Klebsiella*, *Salmonella*, *Eberthella* and *Shigella*. *Loefflerella* previously used by Gay et al. (Agents of Disease and Heat Resistance, Indianapolis, 1935, 782) is here also used as a subgeneric name for the glanders bacillus; and *Chromobacterium* is used for the organisms more properly placed in *Serratia* Bizio.

*Corynebacterium* is transferred from the order *Actinomycetales* to *Eubacteriales* and the family *Corynebacteriaceae* is made to include *Lactobacillus*, *Erysipelothrix* and *Fusobacterium*. Among the *Spirochaetales*, the genus name *Spirochaeta* is displaced by a new generic term, *Ehrenbergia*, and is itself used to displace *Borrelia*.

A seventh order *Rickettsiales* is proposed to include two families: *Rickettsiaceae* with one genus *Rickettsia* da Rocha Lima (Berl. klin. Wchnschr., 1916, 567); and *Bartonellaceae* with the genera, *Bartonella* Strong, Tyrzer, Brues, Sellards and Gastiáburú (Jour. Amer. Med. Assoc., 61, 1913, 1713), and *Grahamella* Brumpt (Bull. Soc. Path. Exot., 4, 1911, 514).

During 1945, Soriano (Ciencia e Investigación, 1, 1945, 92-94 and 146-147; Rev. Argentina de Agronomía, 12, 1945, 120) proposed an arrangement of the Class *Schizomycetes* in which he recognizes a new Order, *Flexibacteriales*, to include the families *Cytophagaceae* and *Beggiatoaceae* and an entirely new Family *Flexibacteriaceae* containing a single genus *Flexibacter*. The latter includes five newly recognized species of flexuous bacteria as follows: *Flexibacter flexilis*, type species, *F. elegans*, *F. giganteus*, *F. aluminosus* and *F. aureus*.

The outline given below shows how this new order and new family are fitted by Soriano into the classification used in the fifth edition of the MANUAL.

#### Class *Schizomycetes*

Subclass <i>Eubacteria</i> . Rigid cells.	Subclass <i>Flexibacteria</i> . Flexuous cells.
Order I. <i>Eubacteriales</i>	Order VI. <i>Flexibacteriales</i>
Order II. <i>Caulobacteriales</i>	Family I. <i>Cytophagaceae</i>
Order III. <i>Rhodobacteriales</i>	Family II. <i>Beggiatoaceae</i>
Order IV. <i>Actinomycetales</i>	Family III. <i>Flexibacteriaceae</i>
Order V. <i>Chlamydobacteriales</i>	Order VII. <i>Myxobacteriales</i>
	Order VIII. <i>Spirochaetales</i>

Prévot (Ann. Inst. Past. 72, 1946, 1) has developed his classification of Class *Actinomycetales*, subdividing it into orders and including several genera not recognized in his 1940 outline. This classification is as follows:

#### Class *Actinomycetales*

Order I <i>Actinobacteriales</i>	New order	Not acid-fast
Family I <i>Spherophoraceae</i>	Family II. <i>Actinomycetaceae</i> .	
Genus I <i>Spherophorus</i>	Genus I <i>Actinomyces</i>	
Genus II <i>Haverhillia</i>	Genus II <i>Proactinomyces</i>	
Genus III <i>Spherotheca</i>	Genus III <i>Corynebacterium</i>	
Genus IV <i>Fusiformis</i>	Genus IV <i>Actinobacterium</i>	
Genus V <i>Fusocillus</i>	Genus V <i>Bifidobacterium</i>	
Genus VI <i>Leptotrichia</i>	Genus VI. <i>Crysiellothrix</i>	
Order II <i>Mycobacteriales</i>	New order	Acid-fast
Genus I <i>Mycobacterium</i>		

This classification differs from that used in this edition of the MANUAL in that it places several genera of Gram-negative organisms in *Actinomycetales*. These are *Spherophorus*, *Haverhillia*, *Spherotheca*, *Fusiformis* and *Fusocillus*, all of which are included here under *Parvobacteriaceae*. *Leptotrichia* which Prévot regards as Gram-negative is generally accepted as being a Gram-positive group. It is discussed in this edition of the MANUAL in connection with the genus *Lactobacillus*.

## HOW BACTERIA ARE NAMED AND IDENTIFIED\*

Some principles of taxonomy and nomenclature. "Taxonomy is that branch of biology that deals with the orderly arrangement of plants and animals" (Johnson, *Taxonomy of the Flowering Plants*, New York, 1931, p. 3).

The necessity for applying names to species or kinds of bacteria is self-evident. It is highly desirable that the name applied to an organism by one person should be understood by others. It is further desirable that as far as practicable all individuals use the same name for the same kind of organism. It is helpful, therefore, if there can be an agreement regarding the method of naming organisms, and as to the correct name for each organism. The term *nomenclature* is applied to the naming of plants and animals, and under this term may be included all discussions as to methods of naming and correctness of particular names.

It is not enough that bacteria be named. Some method of classification of the bacteria is essential if the names are to be rendered accessible and available, and identification of unknown forms be made possible. *Taxonomy* is that branch of biology which treats of classification in accordance with a convention or law. It is apparent that taxonomy must be dependent in part for its satisfactory development upon nomenclature. Even though there may not be agreement among bacteriologists as to the exact classification that is to be used, nevertheless it is highly desirable that there be agreement as to some of the fundamental characteristics of satisfactory biological classifications in general.

What kinds of names are used. Two kinds of names are commonly given to the different kinds of plants and animals, the common, provincial, vernacular or casual names on the one hand and the international or scientific names on the other. These should be carefully differentiated, and their respective advantages and disadvantages noted.

It is inevitable, and on the whole probably desirable, that for each kind of familiar animal or plant in each language there will be coined a name. Usually the name for the same organism will be different in each language. For example, we have in English *Oak*, in German *Eiche*, in Latin *Quercus*, etc. For many uncommon kinds, however, there may be no such vernacular names developed. There have been, of course, many casual or vernacular names given to kinds of bacteria. In English we speak of the tubercle bacillus, the typhoid germ, the gonococcus, the Welch bacillus, the golden

---

\* Contributed by Prof. R. E. Buchanan, Iowa State College, Ames, Iowa, January, 1931; revised, March, 1933.

pus coccus, and many others. Similarly, we find in German Typhusbazillen and in French bacille typhique, enterococcus, etc. The use of these common names offers certain advantages. It does away frequently with the necessity of repeating longer and more formal scientific names. Not infrequently scientific names may be adopted into a language, and converted into vernacular names. For example, the English name *aster* and the scientific generic name *Aster* are applied to the same group. This is frequently a convenience, but there are also some difficulties, which will be emphasized below.

In contrast to common, vernacular or casual names, the scientific name for each kind of organism (each plant or animal) is supposed to be the same in all countries and in all languages. When such a scientific name is used, no question should arise in any language as to what organism is intended. The names thus applied are supposed to conform to certain general rules that have been formulated by international agreement. Obviously the use of such names is advantageous whenever one is desirous of accuracy, and of being definitely understood in all languages. It is further evident that in all questions relating to taxonomy and classification it is highly desirable that the scientific names be used.

**International rules for nomenclature.** In order that there be an international set of scientific names, it is essential that there be an international agreement as to the rules which should govern their creation. Both of the great groups of biologists, the botanists and the zoologists, have met in numerous international congresses in which delegates were accredited by the great botanical and zoological societies, museums, and educational institutions of the world. Codes of nomenclature designed to tell how names shall be manufactured and used, and how to tell which of two or more names that have been used is correct, have been developed by each of these groups. These codes or lists of rules and recommendations are quite similar in essentials for botany and zoology, although they differ in some details.

The question arises: Are either or both of these codes satisfactory or adaptable to the use of bacteriologists. Three views have been expressed by various writers. Some few have suggested that the naming of bacteria cannot well conform to the approved international rules as their classification involves considerations not familiar to botanists and zoologists generally. The second group, also a very small one, has insisted that unicellular forms of life are neither plants or animals, but protista, and that taxonomic rules, etc., should be distinct for this group and coördinate with the corresponding rules for plants and for animals.

The third view, more commonly expressed, is that the bacteria are sufficiently closely related to the plants and animals, so that (in so far as

they apply) the international agreements of the botanists (or zoologists) should be used as a basis for naming them.

International opinion on this topic was finally crystallized by resolutions adopted by the First International Congress of the International Society for Microbiology held in Paris in 1930 and by the Fifth International Botanical Congress held in Cambridge, England in the same year.

The resolutions unanimously adopted by the plenary session of the International Society for Microbiology were in part as follows:

"It is clearly recognized that the living forms with which the microbiologists concern themselves are in part plants, in part animals, and in part primitive. It is further recognized that *in so far as they may be applicable and appropriate* the nomenclatural codes agreed upon by International Congresses of Botany and Zoology should be followed in the naming of micro-organisms. Bearing in mind, however, the peculiarly independent course of development that bacteriology has taken in the past fifty years, and the elaboration of special descriptive criteria which bacteriologists have of necessity developed, it is the opinion of the International Society for Microbiology that the bacteria constitute a group for which special arrangements are necessary. Therefore the International Society for Microbiology has decided to consider the subject of bacterial nomenclature as a part of its permanent program."

The International Society of Microbiologists established a permanent Nomenclature Committee to pass upon suggestions and to make recommendations. This committee is composed of members from all participating nations. Two secretaries were named, one (Dr. St. John-Brooks of the Lister Institute, London, England) to represent primarily medical and veterinary bacteriology, and one (Dr. R. S. Breed, New York State Agricultural Experiment Station, Geneva, New York, U. S. A.) to represent other phases of bacteriology.

The cooperation of the International Botanical Congress was solicited in the naming of this committee. The resolutions were approved by the Section on Bacteriology of the Botanical Congress and the Congress itself incorporated into the Botanical Code certain special provisions relating to the bacteria. It also specifically recognized the International Committee as the body to prepare recommendations relating to bacterial nomenclature.

It is apparent, therefore, that there has been international agreement (in so far as this can be achieved) that bacteriologists should follow the botanical or zoological codes in the naming of bacteria to the extent they are applicable, and that exceptions or new problems should be presented to the International Committee.

These rules are so important in determining the validity of bacterial names that the rules of the Botanical Code are included in somewhat

abridged form in the section that follows this introduction. Any student who has occasion to name a new species or a new genus or determine the validity of a name should familiarize himself with these rules and recommendations.

An effort has been made in the present volume to use nomenclature in conformity with these rules.

**Some general principles of nomenclature.** Every student of bacteriology should be familiar with certain rules of nomenclature if he is to use names intelligently. If he wishes to correct names improperly used or if he desires to name new species, there are additional rules which he must observe.

1. Each distinct kind of bacterium is called a species.

2. To each distinct species a name is given consisting usually of two Latin words, as *Bacillus subtilis*.

3. The first word is the name of the genus or group to which the organism belongs. It is *always* written with a capital letter. It is a Latin or Greek word, or a new word compounded from Latin or Greek roots, or it may be derived from some other language; but this is important, whatever its origin when used as a generic name it must be regarded and treated as a Latin noun. If it is a word not found in classic Latin, it is regarded as modern Latin. Some generic names in bacteriology which are Latin or formed from Latin roots are *Bacillus* (masculine) a small rod; *Cristispira* (feminine) a crested spiral; *Lactobacillus* (masculine) a milk small rod; *Sarcina* (feminine) a packet or bundle. Many others are words from the Greek or compounded from Greek roots, with the words transliterated into Latin letters and endings in conformity with Latin usage; words of Greek origin are *Micrococcus* (masculine) a small grain (sphere); *Bacterium* (neuter) a small rod, *Clostridium* (neuter) a small spindle; *Corynebacterium* (neuter) clubbed small rod; *Actinomyces* (masculine) ray fungus. Other generic names have been given in honor of persons or places as *Beggiatoa* (feminine), *Borrelia* (feminine), *Eberthella* (feminine), *Pasteurella* (feminine), *Erwinia* (feminine), *Zopfius* (masculine).

4. The second word in the scientific name is a *specific* epithet. It is *not* capitalized except that certain authors capitalize species names derived from proper nouns.

It may be:

- (a) An adjective modifying the noun, and indicating by its ending agreement with the generic name in gender, as *Bacterium album* (white *Bacterium*), *Bacillus albus* (white *Bacillus*), *Sarcina alba* (white *Sarcina*), *Eberthella dispar* (the different *Eberthella*), *Bacterium variabile* (the variable *Bacterium*), *Brucella melitensis* (the maltese *Brucella*), *Bacillus teres* (the rounded *Bacillus*), *Bacillus graveolens* (sweet-smelling *Bacillus*).

Typical adjectives		
Masculine	Feminine	Neuter
<i>albus</i>	<i>alba</i>	<i>album</i>
<i>niger</i>	<i>nigra</i>	<i>nigrum</i>
<i>tener</i>	<i>tenera</i>	<i>tenerum</i>
<i>acer</i>	<i>acris</i>	<i>acre</i>
<i>variabilis</i>	<i>variabilis</i>	<i>variabile</i>
<i>dispar</i>	<i>dispar</i>	<i>dispar</i>
<i>coccoides</i>	<i>coccoides</i>	<i>coccoides</i>
<i>aerogenes</i>	<i>aerogenes</i>	<i>aerogenes</i>

(b) An adjective in the form of the present participle of a verb, as *Clostridium dissolvens* (the dissolving *Clostridium*, in the sense of the *Clostridium* which is able to dissolve), *Bacillus adhacens* (the adhering *Bacillus*), *Acetobacter ascendens* (the climbing *Acetobacter*), *Bacillus esterificans* (the ester-producing *Bacillus*). The endings for present participles used as adjectives are the same for all genders. The past participle is used occasionally, as in *Pseudomonas aptata* (the adapted *Pseudomonas*), *Spirillum attenuatum* (the attenuated *Spirillum*).

(c) A noun in the genitive (possessive) modifying the generic name. There is no necessary agreement in gender or number. Examples, *Clostridium welchii* (Welch's *Clostridium*), *Salmonella pullorum* (the *Salmonella* of chicks), *Streptococcus lactis* (the *Streptococcus* of milk), *Brucella abortus* (the *Brucella* of abortion), *Clostridium tetani* (the *Clostridium* of tetanus), *Diplococcus pneumoniae* (the *Diplococcus* of pneumonia), *Salmonella anatum* (the *Salmonella* of ducks).

(d) A noun in apposition, that is, an explanatory noun. This does not agree necessarily with the generic name in gender. This method of naming is relatively not common in bacteriology. Examples are *Actinomyces scabies* (the scurf or scab *Actinomyces*), *Bacillus lacticola* (the milk-dweller bacillus), *Bacillus radiculicola* (the root-dweller bacillus).

5. The author of the name is often indicated following the name of the species, as *Bacillus subtilis* Cohn. Sometimes a name is indicated also in parenthesis, as *Micrococcus luteus* (Schroeter) Cohn. This means that Schroeter first named the species, giving it the name *luteus*, but placed it in another genus (*Bacteridium*). Cohn placed it in a new genus. It should be noted that the name of a person, following the name of an organism is frequently not the person who first discovered or described it, but the person who first gave it the name used. For example, *Clostridium welchii* (Migula) Holland was first described by Dr. Wm. H. Welch, but not named by him. It was named by Migula in honor of Dr. Welch and later it was placed in the genus *Clostridium* by Holland.

6. Sometimes species of bacteria are subdivided into varieties. These are likewise given Latin designations, and the entire name written as:

*Streptococcus lactis* var. *maltigenes* (the *Streptococcus* of milk producing malt flavor).

Some principles of taxonomy. It is important further that the student of bacteriology recognize the meaning of certain terms used regularly in classifications.

(1) Species (plural species). A species of plant (or animal) is assumed above to be one kind of plant. But how much difference must exist between two cultures of bacteria before one is justified in regarding the organisms in them as being of distinct kinds or species? No rule can be laid down. It depends largely upon convenience and a more or less arbitrary decision. As stated by Hitchcock (Descriptive Systematic Botany, New York, 1925, p. 8): "The unit of classification is a coherent group of like individuals, called a species. The term is difficult to define with precision because a species is not a definite entity, but a taxonomic concept." Hucker and Pederson (New York Agric. Exper. Sta. Tech. Bull. 167, 1930, p. 39) state: "The difficulty met with among these lower forms in dividing them into well-defined groups has led many to question whether these small groups or 'species' are natural groups and whether such groups can be considered to be similar to 'species' among higher forms. However this may be, it is necessary to arrange bacteria as well as possible into groups or so-called 'species' for convenience in classification," and again (Hucker, New York Agric. Exper. Sta. Tech. Bull. 100, 1921, 29), "characters applicable to the differentiation of species must evidence a certain amount of constancy when studied over a large series of tests. Furthermore, characters adapted to the differentiation of larger natural groups or genera should, in addition to constancy, show some correlation with other constant characteristics. The presence of this relationship or correlation between characters for the division of genera indicates that the groupings are being made along natural rather than artificial lines."

*Type culture.* It is quite evident that when a new species of bacterium is described, it must include the particular culture from which the species description was made. This original culture is termed the type culture. We may develop a definition as follows:—A species of bacterium is the type culture or specimen together with all other cultures or specimens regarded by an investigator as sufficiently like the type (or sufficiently closely related to it) to be grouped with it. It is self-evident that different investigators may not draw the same boundaries for a given species. This leads to some practical difficulties, but no better definition has been evolved.

There are certain special cases which require brief discussion.

(a) How should one designate the different stages in an organism that exhibits a growth cycle? There seems to be increasing evidence that certain bacteria show cycles in morphology which parallel to some degree those well

known among the fungi. Such, for example, may well be the rough (R) and smooth (S) types described for many bacteria, possibly the filterable stages noted by many authors, the so-called G types, etc. It is evident that an adequate description of any species of bacterium should include a description of each of these stages in the cyclical development wherever such is proved to exist. In all other cases in botany and in zoology which involve growth stages or cycles one stage has been chosen and designated as the mature or adult or perfect stage. In ferns, for example, names and classifications are based largely upon the sporophytic generation, in insects upon the adult or imago, in the rusts upon the stage in which the teliospores are produced. There has been no international agreement as to what stage should be thus designated for the bacteria. Beyond doubt, it would be the stage which is most easily cultured and studied in the laboratory, the stage with which we are best acquainted in the laboratory. It might easily happen in bacteria (as it has with fungi) that two different stages of the life cycle of single species have been described and named as separate species. When the mistake has been discovered, the name given to the mature or perfect stage is the one that is accepted. In general the descriptions given in the present volume are those which may be regarded as belonging to the perfect stage. Unfortunately it is not yet possible accurately to group the stages in many of the bacteria that have definite growth cycles.

It is desirable frequently to designate the stage with which one is working. This may be done by some conventional symbol, as S (smooth type), G (filterable stage), etc.

(b) How should one designate variants which differ in some minor respects from the type, but which do not constitute growth stages? For example, the species *Bacillus subtilis* normally produces endospores. Suppose that an asporogenous race is derived from such, agreeing with the parent culture in all respects, but showing no tendency to revert to spore production. What such an organism should be called is a matter of judgment. It might frequently be designated as an asporogenous strain, or more technically if one desires as a variety. It might be termed, for example, *Bacillus subtilis* var. *asporus*. In other cases such expressions as *Diplococcus pneumoniae* Type I, or the Rawlings strain of the typhoid bacillus may be used.

Unfortunately there is no general agreement upon the exact significance which the word "strain" should have in bacteriology. It is recommended that it refer merely to source, e.g. the Rawlings strain of *Eberthella typhosa*, and that it be never used to connote a biological character. This would not prevent such expressions as "a non-motile strain of *Salmonella suispestifer*", but it would make erroneous a statement to the effect that the A

strain of influenza virus differs from the B strain in certain ways. In other words, "strain" is not a synonym of "type" or "variety". We may have as many yellow strains of the typhoid bacillus as we have of cultures of it, from different sources or specimens.

(2) Genus (plural genera). A genus is a group of related species. In some cases a genus may include only a single species (is said to be *monotypic*) in most cases several to many species are included in a genus. The question asked above may be paraphrased. How close must be the resemblances (how close the relationships) among the species of a group to entitle them to inclusion in the same genus? In other words, how is it possible to delimit accurately the boundaries of a genus? This is a matter on which there is no agreement, and probably can be none. Much of the confusion in modern bacteriological terminology is to be attributed to this fact. Nevertheless, in course of time experience tends to delimit many genera with reasonable accuracy. As stated by Hitchcock (Descriptive Systematic Botany, New York, 1925, p. 9): "Convenience may play a rôle in determining generic lines. Extremely large groups may be broken up on the basis of differences of smaller degree not common to a group of closely allied species, than if the group consisted of a few species. In general, the botanist, in delimiting genera, keeps in mind two important requirements, that of showing natural affinities and that of aiding correct identification." However, a genus may be defined helpfully in another way. One of the species described as belonging to a genus is designated as the *type* species. A genus may be defined then, as including this type species together with such other species as the investigator (or taxonomist) regards as sufficiently closely related. It is apparent that some authors may draw the lines narrowly, others broadly. Some authors, for example, recognize only two genera of rod-shaped bacteria, one for those without endospores (*Bacterium*), and one for those producing endospores (*Bacillus*). These genera thus defined are very large, each containing hundreds, perhaps thousands, of species. Other students break up these large genera into many smaller ones. There is not much point to the question as to which is right and which is wrong. A better question is, which is the more convenient, better represents relationships, better facilitates diagnosis and proves most useful. As organisms become better known, it may be possible through the agency of the International Committee on Nomenclature to reach agreements where lack of agreement leads to serious confusion or misunderstanding.

(3) Family. A family in taxonomy is a group of related genera. In general the name of the family is made from the name or former name of one of their genera by affixing the suffix *-aceae* to the root. The word is regarded as plural. Among bacterial families commonly recognized are *Bacillaceae*, *Bacteriaceae*, *Micrococcaceae*, *Spirochaetaceae*, *Actinomycetaceae*.

(4) **Order.** An order is a group of related families. It is named usually (not always) by substituting the suffix *-ales* for *-aceae* in the name of the type family. Among ordinal names that have been used in bacteriology are *Actinomycetales*, *Spirochaetales*, *Eubacteriales*.

(5) **Class.** A class is a group of related orders. In this treatise it is considered that the bacteria constitute a class of the plant kingdom, and this is named *Schizomycetes*.

(6) **Other categories.** Other *categories* or *ranks* of names are used for higher groups. Sometimes families are divided into sub-families, these into tribes, these into subtribes, and these finally into genera.

**How to identify an organism by name.** One of the main purposes of a manual of determinative bacteriology is to facilitate the finding of the correct scientific name of a bacterium. Such is the purpose of this volume. It is well, however, to note some of the reasons why this result, the identification of an unknown culture, may not eventuate. Among these reasons the following may be listed:

(1) The unknown organism awaiting identification by the investigator may easily be one which has never been named, or perhaps adequately described. For the most part there has been little effort on the part of bacteriologists to describe or name bacteria except as they have been found to have some economic significance or possess some striking or unusual characteristics. It is quite probable that there are many times as many species of bacteria undescribed and named as have been described. Such undescribed species are all about us. It is not surprising, therefore, if one frequently encounters undescribed species. When such unnamed species are encountered, particularly if they are of economic importance or are related to such forms, it is highly desirable that they should be described, named and the results published and made accessible.

(2) The unknown organism may have been described and named in some publication, but the description and name have been over-looked in the preparation of the MANUAL. Perhaps the description has been so inadequate or incomplete that it has not been possible to place it in the classification. It should be noted that the number of species that have been described is so great that no one individual can know them all. Progress in classification comes about largely as the result of the work of specialists in particular groups. For example, Ford made a study of all of the aerobic spore-bearing bacteria which he had secured from various sources. He studied also the descriptions of such bacteria in the literature, and then monographed the group. Similar studies on other groups have resulted in more or less complete monographs. Such, for example, are the monographs on the intestinal group by Welden and Levine, of the acetic bacteria by Hoyer, and Visser 't Hooft, of the cocci by Hucker, of the

pathogenic spore-bearing anaerobes by the English Commission, by Weinberg, and by others, of the red, rod-shaped bacteria by Hefferan and by Breed, of the actinomyces by Waksman and by Lieske, of the root nodule bacteria of legumes by Fred and his co-workers, etc. Unfortunately most groups of bacteria have not thus been monographed. It is evidently the function of a manual such as this to draw largely upon the work of the monographers, and to supplement their achievements as far as possible by less satisfactory consideration of the unmonographed groups.

It is clear that because an organism cannot be identified from this text is not proof that it has not been described and named. The species most closely related may be determined, then the literature searched carefully for species described still more closely related or perhaps one identical.

(3) It is possible, of course, that an error has been made in the selection of the correct name. It is desirable that users of these keys and descriptions should be familiar with the rules governing the correct choice of names, and make suitable corrections where needed.

Steps in determining the name of an organism. The steps in the identification of an unknown organism are usually the following:

- (1) Preparation of an adequate description of the organism.
- (2) Knowledge of construction and use of keys.
- (3) Determination of order, family and genus by use of key.

*Preparation of description of organism.* Before attempting to determine the name of an "unknown" organism an adequate description is essential. Just what characteristics must be emphasized depends upon the group in which the organism falls. It is desirable that the knowledge of the characters of the unknown be as complete as possible.

*Use and construction of keys.* An exceptionally clear and satisfactory discussion of the making and use of keys and synopses is given by Hitchcock (*Descriptive Systematic Botany*, New York, 1925, p. 101). Anyone planning to monograph a group is advised to read this. He states: "A key is an orderly arrangement of a series of contrasting or directly comparable statements, by which groups of the same category may be distinguished and indicated or identified," and "A key is primarily a mechanical device by which one may arrive at the name of the ultimate member of the group." In general the keys used in this MANUAL are *dichotomous*, that is, the successive divisions are in twos, differentiation being into two contrasted groups.

*Determination of order, family and genus by use of keys.* The method of doing this is discussed in the introduction beginning on page 1.

## RULES OF NOMENCLATURE\*

In Paris in 1930, the First International Microbiological Congress voted to follow the rules of nomenclature agreed upon by International Congresses of Botany and Zoology "*in so far as they may be applicable and appropriate.*" The adoption of the date of the publication of *Species Plantarum* by Linnaeus in 1753 as the point of departure for bacteriological nomenclature was recommended. This recommendation was approved by the plenary session of the Microbiological Congress (Proc. 1<sup>st</sup> Cong. Internat. Microbiol., Paris, 1930, 2, 1932, 519) and by the plenary session of the Botanical Congress (Rept. Proc. 5th Internat. Bot. Cong., 1930, Cambridge, 1931, p. 16 and 28).

This Congress also provided for the organization of an International Committee on Bacteriological Nomenclature with two permanent secretaries:

1. To represent primarily medical and veterinary bacteriology,—Dr. R. St. John-Brooks, Lister Institute, London, England
2. To represent primarily other phases of bacteriology,—Dr. R. S. Breed, Experiment Station, Geneva, New York, U. S. A.

During the years that have elapsed since its appointment, this Committee has organized and has taken various actions in the interest of a more stable nomenclature and classification. Some of these have been completed and accepted by the Second International Congress of Microbiology held in London, 1936. These completed actions are quoted below, and are incorporated into the classification used in the descriptive portion of the **MANUAL**.

The International Rules of Botanical Nomenclature were originally adopted by the International Botanical Congresses of Vienna (1903) and Brussels (1910). They were modified by the Cambridge Congress (1930) so as to accept the type method, and validate species descriptions of bacteria unaccompanied by a Latin diagnosis. Some further but less important modifications were made at the Amsterdam Congress (1935) (See Sprague, *Science*, 83, 1936, 416).

The following are the most important of the rules that are of interest to bacteriologists taken from the latest available edition of the Botanical Code (Gustav Fischer, Jena, 1935). Sections that were newly adopted or amended by the Amsterdam Botanical Congress (1935) are indicated in the text.

## INTERNATIONAL RULES OF BOTANICAL NOMENCLATURE, 1930-1935

### *Chapter I. General Considerations and Guiding Principles (Art. 1-9)*

Art. 1. Botany cannot make satisfactory progress without a precise system of nomenclature, which is used by the great majority of botanists in all countries.

Art. 2. The precepts on which this precise system of botanical nomenclature is based are divided into *principles*, *rules*, and *recommendations*. The principles (Art. 1-9, 10-14 15-19) form the basis of the rules and recommendations. The object of the rules (Art. 19-74) is to put the nomenclature of the past into order and to provide for that of the future. They are always retroactive; names or forms of nomenclature contrary to a rule (illegitimate names or forms) cannot be maintained. The recommendations deal with subsidiary points, their object being to bring about greater uniformity and clearness in future nomenclature: names or forms contrary to a recommendation cannot on that account be rejected, but they are not examples to be followed.

Art. 3. The rules of nomenclature should be simple and founded on considerations sufficiently clear and forcible for everyone to comprehend and be disposed to accept.

Art. 4. The essential points in nomenclature are: (1) to aim at fixity of names; (2) to avoid or to reject the use of forms and names which may cause error or ambiguity or throw science into confusion.

Next in importance is the avoidance of all useless creation of names.

Other considerations, such as absolute grammatical correctness, regularity or euphony of names, more or less prevailing custom, regard for persons, etc., notwithstanding their undeniable importance, are relatively accessory.

Art. 5. In the absence of a relevant rule, or where the consequences of rules are doubtful, established custom must be followed.

Art. 7. Scientific names of all groups are usually taken from Latin or Greek. When taken from any language other than Latin, or formed in an arbitrary manner, they are treated as if they were Latin. Latin terminations should be used so far as possible for new names.

Art. 8. Nomenclature deals with: (1) the *terms* which denote the rank of taxonomic groups (Art. 10-14), (2) the *names* which are applied to the individual groups (Art. 15-72).

Art. 9. The rules and recommendations of botanical nomenclature apply to all groups of the plant kingdom, recent and fossil, with certain distinctly specified exceptions.

### *Chapter II. Categories of Taxonomic Groups, and the Terms Denoting Them (Art. 10-14, Rec. I, II)*

Art. 10. Every individual plant belongs to a species (*species*), every species to a genus (*genus*), every genus to a family (*familia*), every family to an order (*orda*) every order to a class (*classis*), every class to a division (*diviso*).

### *Chapter III. Names of Taxonomic Groups (Art. 15-72, Rec. III-L)*

#### *Section 1. General Principles: Priority (Art. 15-17, Rec. III)*

Art. 15. The purpose of giving a name to a taxonomic group is not to indicate the characters or the history of the group, but to supply a means of referring to it.

Art. 16. Each group with a given circumscription, position, and rank can bear only one valid name, the earliest that is in accordance with the Rules of Nomenclature.

*Section 2. The Type Method (Art. 18, Rec. IV-VII)*

Art. 18. The application of names of taxonomic groups is determined by means of *nomenclatural types*. A nomenclatural type is that constituent element of a group to which the name of the group is permanently attached, whether as an accepted name or as a synonym. The name of a group must be changed if the type of that name is excluded (see Art. 66).

*Section 3. Limitation of the Principle of Priority: Publication, Starting-points, Conservation of Names (Art. 19-22)*

Art. 19. A name of a taxonomic group has no status under the Rules, and has no claim to recognition by botanists, unless it is validly published (see Art. 37).

Art. 20. Legitimate botanical nomenclature begins for the different groups of plants at the following dates:

(h) *Myzomycetes*, 1753 (Linnaeus, *Species Plantarum*, ed. 1).\*

Art. 21. However, to avoid disadvantageous changes in the nomenclature of genera by the strict application of the Rules of Nomenclature, and especially of the principle of priority in starting from the dates given in Art. 20, the Rules provide a list of names which must be retained as exceptions. These names are by preference those which have come into general use in the fifty years following their publication, or which have been used in monographs and important floristic works up to the year 1890.

*Section 4. Nomenclature of the Taxonomic Groups According to Their Categories (Art. 23-35, Rec. VII-XX)*

1. *Names of Groups above the Rank of Family.*

Rec. IX. Orders are designated preferably by the name of one of their principal families with the ending *-ales*.

2. *Names of Families and Subfamilies, Tribes, and Sub-tribes.*

Art. 23. Names of families are taken from the name or former name of one of their genera and end in *-aceae*

Art. 24. Names of subfamilies (*subfamiliae*) are taken from the name of one of the genera in the group, with the ending *-oideae*, similarly for tribes (*tribus*), with the ending *-eae*, and for subtribes (*subtribus*) with the ending *-inae*.

3. *Names of Genera and Subdivisions of Genera.*

Art. 25. Names of genera are substantives (or adjectives used as substantives), in the singular number and written with an initial capital, which may be compared with our family names. These names may be taken from any source whatever, and may even be composed in an absolutely arbitrary manner

*Recommendation X.* Botanists who are forming generic names show judgment and taste by attending to the following recommendations:

(a) Not to make names long or difficult to pronounce.

(b) Not to dedicate genera to persons quite unconnected with botany or at least with natural science, nor to persons quite unknown.

(c) Not to take names from barbarous languages, unless those names are frequently cited in books of travel, and have an agreeable form that is readily adaptable to the Latin tongue and to the tongues of civilized countries.

---

\* See page 48 for action on date for *Schizomycetes*.

- (d) To indicate, if possible, by the formation or ending of the name the affinities or analogies of the genus
- (e) To avoid adjectives used as nouns.
- (f) Not to give a genus a name whose form is rather that of a subgenus or section (e.g. *Eusideroxylon*, a name given to a genus of *Lauraceae*. This, however, being legitimate, cannot be altered).
- (g) Not to make names by combining words from different languages (*nomina hybrida*).

#### 4. Names of Species (binary names).

Art. 27. Names of species are binary combinations consisting of the name of the genus followed by a single specific epithet. If an epithet consists of two or more words, these must either be united into one or joined by a hyphen. Symbols forming part of specific epithets proposed by Linnaeus must be transcribed.

The specific epithet, when adjectival in form and not used as a substantive, agrees with the generic names.

#### Recommendations.

XIII. The specific epithet should, in general, give some indication of the appearance, the characters, the origin, the history or the properties of the species. If taken from the name of a person it usually recalls the name of the one who discovered or described it, or was in some way concerned with it.

XIV Names of men and women, and also of countries and localities used as specific epithets, may be substantives in the genitive (*Clusia, saharae*) or adjectives (*Clusianus, dahuricus*). It will be well, in the future, to avoid the use of the genitive and the adjectival form of the same epithet to designate two different species of the same genus e.g. *Lysimachia Hemsleyana* Maxim. (1891), and *L. Hemsleyi* Franch. (1895).

XV. In forming specific epithets botanists will do well to have regard also to the following recommendations:

- (a) To avoid those which are very long and difficult to pronounce.
- (b) To avoid those which express a character common to all, or nearly all, the species of a genus.
- (c) To avoid using the names of little-known or very restricted localities, unless the species is quite local.
- (d) To avoid, in the same genus, epithets which are very much alike, especially those which differ only in their last letters
- (e) Not to adopt unpublished names found in travellers' notes or in herbaria, attributing them to their authors, unless these have approved publication.
- (f) Not to name a species after a person who has neither discovered, nor described, nor figured, nor in any way studied it.
- (g) To avoid epithets which have been used before in any closely-allied genus.
- (h) To avoid specific epithets formed of two or more (hyphenated) words.
- (i) To avoid epithets which have the same meaning as the generic name (pleonasm).

#### Section 5. Conditions of Effective Publication (Art. 36)

Art. 36. Publication is effected, under these Rules, either by sale or distribution of printed matter or indelible autographs to the general public, or to specified representative botanical institutions.

No other kind of publication is accepted as effective: communication of new names at a public meeting, or the placing of names in collections or gardens open to the public, does not constitute effective publication.

*Section 6. Conditions and Dates of Valid Publication of  
Names (Art. 37-45, Rec. XXI-XXIX)*

Art. 37. A name of a taxonomic group is not validly published unless it is both (1) effectively published (see Art. 36), and (2) accompanied by a description of the group or by a reference to a previously and effectively published description of it.

Art. 38. From January 1, 1935, names of new groups of recent plants, *the Bacteria excepted*, are considered as validly published only when they are accompanied by a Latin diagnosis.

Art. 40. A name of a taxonomic group is not validly published when it is merely cited as a synonym.

Art. 42. A name of a genus is not validly published unless it is accompanied (1) by a description of the genus, or (2) by the citation of a previously and effectively published description of the genus under another name, or (3) by a reference to a previously and effectively published description of the genus as a subgenus, section or other subdivision of a genus.

Art. 43. The name of a monotypic new genus based on a new species is validated (1) by the provision of a combined generic and specific description, (2) by the provision of a plate with analyses showing essential characters, but this applies only to plates and generic names published before January 1, 1908.

Art. 44. The name of a species or of a subdivision of a species is not validly published unless it is accompanied (1) by a description of the group, or (2) by the citation of a previously and effectively published description of the group under another name, or (3) by a plate or figure with analyses showing essential characters, but this applies only to plates or figures published before January 1, 1908.

Art. 45. The date of a name or of an epithet is that of its valid publication (see Art. 19, 36). For purposes of priority, however, only legitimate names and epithets published in legitimate combinations are taken into consideration (see Art. 60). In the absence of proof to the contrary, the date given in the work containing the name or epithet must be regarded as correct.

Botanists will do well in publishing to conform to the following recommendations:

XXI. Not to publish a new name without clearly indicating whether it is the name of a family or a tribe, a genus or a section, a species or a variety, briefly, without expressing an opinion as to the rank of the group to which the name is given.

Not to publish the name of a new group without indicating its type (see Recommendation IV).

XXII. To avoid publishing or mentioning in their publications unpublished names which they do not accept, especially if the persons responsible for these names have not formally authorized their publication (see Recommendation XV (e)).

XXVI. To give the etymology of new generic names and also of new epithets when the meaning of these is not obvious.

XXVII. To indicate precisely the date of publication of their works and that of the placing on sale or the distribution of named and numbered plants when these are accompanied by printed diagnoses. In the case of a work appearing in parts, the last published sheet of the volume should indicate the precise dates at which the different fascicles or parts of the volumes were published as well as the number of pages in each.

XXVIII. When works are published in periodicals, to require the publisher to indicate on the separate copies the date (year and month) of publication and also the title of the periodical from which the work is extracted.

XXIX. Separate copies should always bear the pagination of the periodical of which they form a part; if desired they may also bear a special pagination.

*Section 7. Citation of Authors' Names for Purposes of Precision (Art. 46-49, Rec. XXX-XXXII)*

Art. 46. For the indication of the name (unitary, binary, or ternary) of a group to be accurate and complete, and in order that the date may be readily verified it is necessary to cite the author who first published the name in question.

Art. 47. An alteration of the diagnostic characters or of the circumscription of a group does not warrant the citation of an author other than the one who first published its name.

When the changes have been considerable, an indication of their nature and of the author responsible for the change is added, the words *mutatis charact.*, or *pro parte*, or *excl. gen.*, *excl. sp.*, *excl. var.*, or some other abridged indication being employed.

Art. 48. When a name of a taxonomic group has been proposed but not published by one author, and is subsequently validly published and ascribed to him (or her) by another author who supplied the description, the name of the latter author must be appended to the citation with the connecting word "*ex.*"

If it is desirable or necessary to abbreviate such a citation, the name of the publishing author, being the more important, must be retained.

When a name and description by one author are published by another author, the word *apud* is used to connect the names of the two authors, except where the name of the second author forms part of the title of a book or periodical in which case the connecting word *in* is used instead.

Art. 49. When a genus or a group of lower rank is altered in rank but retains its name or epithet, the original author must be cited in parenthesis, followed by the name of the author who effected the alteration. The same holds when a subdivision of a genus, a species, or a group of lower rank is transferred to another genus or species with or without alteration of rank.

*Section 8. Retention of Names or Epithets of Groups which are Remodelled or Divided (Art. 50-52)*

Art. 50. An alteration of the diagnostic characters, or of the circumscription of a group, does not warrant a change in its name, except in so far as this may be necessitated (1) by transference of the group (Art. 53-55), or (2) by its union with another group of the same rank (Art. 56-57), or (3) by a change of its rank (Art. 58).

Art. 51. When a genus is divided into two or more genera, the generic name must be retained for one of them, or (if it has not been retained) must be re-established. When a particular species was originally designated as the type, the generic name must be retained for the genus including that species. When no type was designated, a type must be chosen according to the regulations which will be given (Appendix I).\*

Art. 52. When a species is divided into two or more species, the specific epithet must be retained for one of them, or (if it has not been retained) must be re-established. When a particular specimen was originally designated as the type, the specific epithet must be retained for the species including that specimen. When no type was designated, a type must be chosen according to the regulations to be given (Appendix I).

---

\* Appendix I has not been published as yet. See Type Basis Code, p. 61.

*Section 9. Retention of Names or Epithets of Groups Below the Rank of Genus on Transference to Another Genus or Species (Art. 53-55)*

Art. 53. When a subdivision of a genus is transferred to another genus (or placed under another generic name for the same genus) without change of rank, its subdivisional name must be retained, or (if it has not been retained) must be re-established unless one of the following obstacles exists (1) that the resulting association of names has been previously published validly for a different subdivision, or (2) that there is available an earlier validly published sub-divisional name of the same rank

Art. 54. When a species is transferred to another genus (or placed under another generic name for the same genus), without change of rank, the specific epithet must be retained or (if it has not been retained) must be re-established, unless one of the following obstacles exists (1) that the resulting binary name has been previously and validly published for a different species, (2) that there is available an earlier validly published specific epithet

"When, on transference to another genus, the specific epithet has been applied erroneously in its new position to a different plant, the new combination must be retained for the plant on which the epithet was originally based, and must be attributed to the author who first published it" (Accepted in this revised form at the Amsterdam Botanical Congress, 1935)

Art. 55. When a variety or other subdivision of a species is transferred, without change of rank, to another genus or species (or placed under another generic or specific name for the same genus or species), the original subdivisional epithet must be retained or (if it has not been retained) must be re-established, unless one of the following obstacles exists (1) that the resulting ternary combination has been previously and validly published for a subdivision based on a different type, even if that subdivision is of a different rank; (2) that there is an earlier validly published subdivisional epithet available

When the epithet of a subdivision of a species, on transference to another species, has been applied erroneously in its new position to a different plant, the epithet must be retained for the plant on which the group was originally based.

Example. The variety *micranthum* Gren. & Godf. (*Fl. France*, i, 171 1817) of *Helianthemum italicum* Pers., when transferred as a variety to *H. penicillatum* Thunb., retains its varietal epithet, becoming *H. penicillatum* var. *micranthum* (Gren. & Godr.) Grosser (in *Engl. Pflanzenreich*, Heft 14, 115 1903)

*Section 10. Choice of Names when Two Groups of the Same Rank are United, or in Fungi with a Pleomorphic Life-cycle (Art. 56, 57, Rec. XXXIII-XXXV)*

Art. 56. When two or more groups of the same rank are united, the oldest legitimate name or (in species and their subdivisions) the oldest legitimate epithet is retained. If the names or epithets are of the same date, the author who unites the groups has the right of choosing one of them. The author who first adopts one of them, definitely treating another as a synonym or referring it to a subordinate group, must be followed

Art. 57. Among Fungi with a pleomorphic life-cycle the different successive states of the same species (*anamorphoses*, *stages*) can bear only one generic and specific name (binary), that is the earliest which has been given, starting from Fries, *Systema*, or Fries, *Synopsis*, to the state containing the form which it has been agreed to call the perfect form, provided that the name is otherwise in conformity with the Rules. The perfect state is that which ends in the ascus stage in the *Ascomycetes*,

in the basidium, in the *Basidiomycetes*, in the teleutospore or its equivalent in the *Uredinales*, and in the spore in the *Ustilaginales*.

Generic and specific names given to other states have only a temporary value. They cannot replace a generic name already existing and applying to one or more species, any one of which contains the "perfect" form.

The nomenclature of Fungi which have not a pleomorphic life-cycle follows the ordinary rules.

### Section 11. Choice of Names when the Rank of a Group is Changed

Art. 58. When a tribe becomes a family, when a subgenus or section becomes a genus, when a subdivision of a species becomes a species, or when the reverse of these changes takes place, and in general when a group changes its rank, the earliest legitimate epithet given to the group in its new rank is valid, unless that name or the resulting association or combination is a later homonym (see Art. 60, 61).

### Section 12. Rejection of Names (Art. 59-69, Rec. XXXVII)

Art. 59. A name or epithet must not be rejected, changed, or modified merely because it is badly chosen, or disagreeable, or because another is preferable or better known (see also Art. 69).

Art. 60. A name must be rejected if it is illegitimate (see Art. 2). The publication of an epithet in an illegitimate combination must not be taken into consideration for purposes of priority, "except as indicated in Art. 61." (Added at the Amsterdam Botanical Congress, 1935.)

A name is illegitimate in the following cases:

(1) If it was superfluous when published, i.e., if there was a valid name (see Art. 16) for the group to which it was applied, with its particular circumscription, position and rank.

(2) If it is a binary or ternary name published in contravention of Art. 16, 50, 52, or 54, i.e., if its author did not adopt the earliest legitimate epithet available for the group with its particular circumscription, position, and rank.

(3) If it is a later homonym (see Art. 61) (except as regards Art. 54 and 55).

(4) If it is a generic name which must be rejected under Art. 67.

(5) If its specific epithet must be rejected under Art. 68.

Art. 61. A name of a taxonomic group is illegitimate and must be rejected if it is a later homonym, that is, if it duplicates a name previously and validly published for a group of the same rank based on a different type. Even if the earlier homonym is illegitimate, or is generally treated as a synonym on taxonomic grounds, the later homonym must be rejected. "When an author simultaneously publishes the same new name for more than one group, the first author who adopts one of them, or substitutes another name for one of them, must be followed." (Added at the Amsterdam Botanical Congress, 1935.)

Art. 62. A name of a taxonomic group must be rejected if, owing to its use with different meanings, it becomes a permanent source of confusion or error. A list of names to be abandoned for this reason (*Nomina ambigua*) will form Appendix IV.\*

Art. 63. A name of a taxonomic group must be rejected when its application is uncertain (*Nomen dubium*): e.g., *Errum soloniense* L. (*Cent. II. Pl. 28: 1756*) is a name the application of which is uncertain; it must, therefore, be rejected (see Schinz and Thell in *Vierteljahrsschr. Nat. Ges. Zürich*, viii, 71 1913).

---

\* Appendix IV has not been published as yet.

Art. 61. A name of a taxonomic group must be rejected if the characters of that group were derived from two or more entirely discordant elements, especially if those elements were erroneously supposed to form part of the same individual.

A list of names to be abandoned for this reason (*Nomina confusa*) will form Appendix VI.\*

Art. 65. A name or epithet of a taxonomic group must be rejected when it is based on a monstrosity.

Art. 66. The name of an order, suborder, family or subfamily, tribe or subtribe must be changed when it is taken from the name of a genus which is known not to belong to the group in question—e.g. if the genus *Portulaca* were excluded from the family now known as *Portulacaceae*, the residual group could no longer bear the name *Portulacaceae*, and would have to be renamed.

Art. 67. Names of genera are illegitimate in the following special cases and must be rejected:

- (1) When they are merely words not intended as names. e.g. *Anonymous* Walt. (Fl. Carol. 2, 4, 9, etc. 1788) must be rejected as being a word applied to 28 different genera by Walter to indicate that they were without names.
- (2) When they coincide with a technical term currently used in morphology unless they were accompanied, when originally published, by specific names in accordance with the binary method of Linnaeus. On and after Jan. 1, 1912, all new generic names coinciding with such technical terms are unconditionally rejected.
- (3) When they are unitary designations of species. e.g. Ehrhart (*Phytophylacium*: 1780; and *Beitr.* iv, 145–150. 1795) proposed unitary names for various species known at that time under binary names: e.g. *Phaeocephalum* for *Schoenus fuscus*, and *Leptostachys* for *Carex leptostachys*. These names, which resemble generic names, should not be confused with them, and must be rejected, unless they have been published as generic names by a subsequent author.
- (4) When they consist of two words, unless these words were from the first combined into one, or joined by a hyphen.

Art. 68. Specific epithets are illegitimate in the following cases and must be rejected:

- (1) When they are merely words not intended as names.
- (2) When they are merely ordinal adjectives being used for enumeration.
- (3) When they exactly repeat the generic name with or without the addition of a transcribed symbol.
- (4) When they were published in works in which the Linnæan system of binary nomenclature for species was not consistently employed.

Art. 69. In cases foreseen in Art. 60–68 the name or epithet to be rejected is replaced by the oldest legitimate name, or (in a combination) by the oldest legitimate epithet. If none exists, a new name or epithet must be chosen. Where a new epithet is required, an author may, if he wishes, adopt an epithet previously given to the group in an illegitimate combination, if there is no obstacle to its employment in the new position or sense.

#### Section 15. Orthography of Names (Art. 70–71, Rec. XXXVIII–XLIV)

Art. 70. The original spelling of a name or epithet must be retained, except in the case of a typographic error, or of a clearly unintentional orthographic error. When the difference between two generic names lies in the termination, these names must

\* Appendix VI has not been published as yet.

be regarded as distinct, even though differing by one letter only. This does not apply to mere orthographic variants of the same name.

Note 1. The words "original spelling" in this Article mean the spelling employed when the name was validly published.

2. The use of a wrong connecting vowel or vowels (or the omission of a connecting vowel in a specific epithet, or in that of a subdivision of a species) is treated as an unintentional orthographic error which may be corrected (see Rec. XLIV). "The liberty of correcting a name must be used with reserve, especially if the change affects the first syllable, and above all the first letter of the name." (Added at the Amsterdam Botanical Congress, 1935.)
3. In deciding whether two or more slightly different names should be treated as distinct or as orthographical variants, the essential consideration is whether they may be confused with one another or not: if there is serious risk of confusion, they should be treated as orthographic variants. Doubtful cases should be referred to the Executive Committee.
4. Specific and other epithets of Greek origin differing merely by having Greek and Latin terminations respectively are orthographic variants. Epithets bearing the same meaning and differing only slightly in form are (considered as) orthographic variants. The genitive and adjectival forms of a personal name are, however, treated as different epithets (e.g. *Lysimachia Hemsleyana* and *L. Hemsleyi*).

#### Recommendations:

XXXVIII. When a new name is derived from a Greek word containing the *spiritus asper* (rough breathing), this should be transcribed as the letter h.

XXXIX. When a new name for a genus, subgenus or section is taken from the name of a person, it should be formed in the following manner—

- (a) When the name of the person ends in a vowel the letter *a* is added (thus *Bouteloua* after Boutelou; *Ottoa* after Otto; *Sloanea* after Sloane), except when the name already ends in *a*, when *ea* is added (e.g. *Collaea* after Colla).
- (b) When the name of the person ends in a consonant, the letters *ia* are added (e.g. *Magnusia* after Magnus, *Ramondia* after Ramond), except when the name ends in *er*, when *a* is added (e.g. *Kernera* after Kerner).
- (c) The syllables which are not modified by these endings, retain their original spelling, even with the consonants *k* and *w* or with groupings of vowels which were not used in classical Latin. Letters foreign to botanical Latin should be transcribed, and diacritic signs suppressed. The Germanic *ā*, *ō*, *ū* become *ae*, *oe*, *ue*, the French *ê*, *è*, *é* become generally *e*. In works in which diphthongs are not represented by special type, the diaeresis sign should be used where required, e.g., *Cephaëllis*, not *Cephaclis*.
- (d) Names may be accompanied by a prefix or a suffix, or modified by anagram or abbreviation. In these cases they count as different words from the original name.

Examples: *Durvillea* and *Urvillea*; *Lapeyrousea* and *Peyrousea*; *Englera*, *Englerastrum* and *Englerella*; *Bouchea* and *Ubochea*; *Gerardia* and *Graderia*.

XL. When a new specific or other epithet is taken from the name of a man, it should be formed in the following manner:—

- (a) When the name of the person ends in a vowel, the letter *i* is added (thus *Glazioui* from Glaziou, *Bureaui* from Bureau), except when the name ends in *a*, when *e* is added (thus *balansae* from Balansa).

- (b) When the name ends in a consonant, the letters *ii* are added (thus *Magnusii* from *Magnus*, *Ramondii* from *Ramond*), except when the name ends in *-er* when *i* is added (thus *Kernerii* from *Kerner*).
- (c) The syllables which are not modified by these endings retain their original spelling, even with the consonants *k* or *w* or with groupings of vowels which were not used in classical Latin. Letters foreign to botanical Latin should be transcribed and diacritic signs suppressed. The Germanic *a*, *o*, *u* become *ae*, *oe*, *ou*, the French *ê*, *è*, *é* become generally *e*. The diacresis sign should be used where required.
- (d) When epithets taken from the name of a person have an adjectival form they are formed in a similar way (e.g. *Geranium Robertianum*, *Verbena Hasslerana*).

XLII. The same provisions apply to epithets formed from the names of women. When these have a substantival form they are given a feminine termination (e.g. *Cypripedium Hookerae*, *Rosa Beatricis*, *Scabiosa Olgaë*, *Omphalodes luciliae*).

XLIII. The specific (or other) epithets should be written in conformity with the original spelling of the words from which they are derived and in accordance with the rules of Latin and latinization.

Examples *silvestris* (not *sylvestris*) *sinensis* (not *chinensis*).

XLIII. Specific (or other) epithets should be written with a small initial letter, except those which are derived from names of persons (substantives or adjectives), or are taken from generic "or vernacular" names (substantives or adjectives). (Emended Amsterdam Botanical Congress, 1935. See page 61 for actions taken by Second International Microbiological Congress, London, 1936 governing Bacteriological Nomenclature.)

XLIV. In the formation of specific (or other) epithets composed of two or several roots taken from Latin or Greek, the vowel placed between the two roots becomes a connecting vowel, in Latin *i*, in Greek *o*, thus *menthifolia*, *salsifolia*, not *menthaefolia*, *saltiaefolia*. When the second root begins with a vowel and euphony requires, the connecting vowel should be eliminated (e.g. *lepidantha*). The connecting vowels *ae* should be retained only where this is required for etymological reasons (e.g. *caricaciformis* from *Carica*, in order to avoid confusion with *cariciformis* from *Carex*). In certain compounds of Greek words no connecting vowel is required, e.g. *brachycarpus* and *glycylyphyllus*.

#### Section 14. Gender of Generic Names

Art. 72. The gender of generic names is governed by the following regulations:—

- (1) "A Greek or a Latin word adopted as a generic name retains its classical gender. In cases where the classical gender varies, the author has the right of choice between the alternative genders. In doubtful cases, general usage should be followed." "The following names, however, whose classical gender is masculine, are treated as feminine in accordance with historic usage: *Adonis*, *Orchis*, *Stachys*, *Diospyros*, *Strychnos*, *Hemerocallis* (m. in Sp. Pl., Lat. and Gr. *hemerocallus* n.) is also treated as feminine to bring it into conformity with all other generic names ending in *is*." (Emended Amsterdam Botanical Congress, 1935.) See Van Eseltine, Jour. Bact., 29, 1933, 569, for discussion of the gender of generic names used for bacteria.
- (2) Generic names which are modern compounds formed from two or more Greek or Latin words take the gender from the last. If the ending is altered, however, the gender will follow it.
- (3) Arbitrarily formed generic names or vernacular names used as generic names take the gender assigned to them by their authors. Where the original

author has failed to indicate the gender, the next subsequent author has the right of choice.

*Section 15. Various Recommendations (Rec. XLV-L)*

XLV. When writing in modern languages botanists should use Latin scientific names or those immediately derived from them, in preference to names of another kind or origin (popular names). They should avoid the use of the latter unless these are very clear and in common use.

XLVII. Only the metric system should be used in botany for reckoning weights and measures. The foot, inch, line, pound, ounce, etc., should be rigorously excluded from scientific language.

Altitude, depth, rapidity, etc., should be measured in meters. Fathoms, knots, miles, etc., are terms which should disappear from scientific language.

XLVIII. Very minute dimensions should be reckoned in  $\mu$  (micromillimeters, microns, or thousandths of a millimeter) and not in fractions of millimeters or of lines, etc.. fractions encumbered with ciphers and commas easily give rise to mistakes.

XLIX. Authors should indicate clearly and precisely the scale of the figures which they publish.

L. Temperatures should be expressed in degrees of the centigrade thermometer of Celsius.

*Chapter IV. Interpretation and Modification of the Rules (Art. 73, 74)*

Art. 73. A small permanent International Executive Committee is established with functions including the following:

- (1) Interpreting the Rules in doubtful cases, and issuing considered "Opinions" on the basis of the evidence submitted.
- (2) Considering *Nomina conservanda*, *Nomina ambigua*, *Nomina dubia* and *Nomina confusa*, and making recommendations thereon to the next International Botanical Congress
- (3) Considering all proposals for the modification of the Rules and reporting thereon to the next Congress.
- (4) Reporting on the effects of modifications of the Rules accepted at the preceding Congress.

Art. 74. These Rules can be modified only by competent persons at an International Botanical Congress convened for the express purpose. Modifications accepted at one Congress remain on trial until the next Congress, at which they will receive sanction unless undesirable consequences, reported to the Executive Committee, show need for further amendment or rejection.

Eight appendices have been or are to be prepared for this Code as follows: (1) †Regulations for determining types, (2) †*Nomina conservanda familiarum*, (3) \**Nomina generica conservanda*, (4) †*Nomina ambigua*, (5) †*Nomina dubia*, (6) †*Nomina confusa*, (7) \*Representative botanical institutions recognized under Art. 34, (8) †Nomenclature of garden plants.

Unfortunately the first appendix which is of greatest interest to bacteriologists has not been prepared. As many bacteriologists, especially those in other countries, have not caught the significance of the type species

\* These appendices have been prepared.

† These appendices have not been published as yet.

concept as a means of defining bacterial genera, the reader is referred to the writings of Hitchcock (Amer. Jour. Bot., 8, 1921, 251; Descriptive Systematic Botany, New York, 1925) for an excellent exposition of the value of this idea to systematists.

Hitchcock (1921, p. 252) explains this concept briefly as follows: "The old concept was that a genus was a group of species having a given combination of characters; a species, similarly, a group of specimens. The new type concept is that, from the nomenclatural standpoint, a genus is a group of species allied to the type species; a species, a group of individuals similar to the type specimen."

Rules for determining types taken from the Type Basis Code of Nomenclature (Science, 49, 1919, 333, 53, 1921, 312) drawn up by a Committee of which Hitchcock was Chairman are quoted as these are the most authoritative rules thus far available.

*Type Basis Code of Nomenclature (Hitchcock et al.)*

Article 4. The nomenclatural type species of a genus is the species or one of the species included when the genus was originally published.

If a genus included but one species when originally published, this species is the type.

When more than one species is included in the original publication of the genus, the type is determined by the following rules

(a) When, in the original publication of a genus, one of the species is definitely designated as type, this species shall be accepted as the type regardless of other considerations.

If *typicus* or *typus* is used as a new specific name for one of the species, this species shall be accepted as the type as if it were definitely designated

(b) The publication of a new generic name as an avowed substitute for an earlier

synonym, that species is to be accepted as the type.

(d) If a genus, when originally published, includes more than one species, and no species is definitely designated as type, nor indicated according to (c), the choice of the type should accord with the following principles.

1. Species inquirendae or species doubtfully referred to the genus, or mentioned as in any way exceptional are to be excluded from consideration in selecting the type
2. Genera of the first edition of Linnaeus's "Species Plantarum" (1753) are usually typified through the citations given in the fifth edition of his "Genera Plantarum" (1754) except when inconsistent with the preceding articles

## RECOMMENDATIONS

Article 5. In the future it is recommended that authors of generic names definitely designate type species; and that in the selection of types of genera previously published, but of which the type would not be indicated by the preceding rules, the following points be taken into consideration:

(a) The type species should usually be the species or one of the species which the author had chiefly in mind. This is often indicated by

1. A closer agreement with the generic description.

2. Certain species being figured (in the same work).

3. The specific name, such as *vulgaris*, *communis*, *medicinalis* or *officinalis*.

(b) The type species should usually be the one best known to the author. It may be assumed that an indigenous species (from the standpoint of the author), or an economic species, or one grown in a botanical garden and examined by the author, would usually represent an author's idea of a genus.

(c) In Linnaean genera the type should usually be chosen from those species included in the first technical use of the genus in pre-Linnaean literature.

(d) The types of genera adopted through citations of non-binomial literature (with or without change of name) should usually be selected from those of the original species which received names in the first binomial publication.

(e) The preceding conditions having been met, preference should be shown for a species which will retain the generic name in its most widely used sense, or for one which belongs to a division of the genus containing a larger number of species, or, especially in Linnaean genera, for the historically oldest species.

(f) Among species equally eligible, the preference should be given to the first known to have been designated as the type.

(g) If it is impossible to select a type under the conditions mentioned above, the first of equally eligible species should be chosen.

While the rules and recommendations of the above botanical codes are applicable in general to bacteria and related microorganisms, the fact that these are not infallible is evident because the rules developed independently by zoologists (see Proc. Biol. Soc. Washington, 39, 1926, 75, for the latest Code of Zoological Nomenclature) frequently follow a quite different course. In some cases at least the zoological rules will appeal to microbiologists as more likely to produce uniformity of usage than the botanical rules.

For example, microbiologists assembled at the Second International Microbiological Congress in London, 1936 accepted (Jour. Bact., 33, 1937, 445) Art. 13 of the International Rules of Zoological Nomenclature as preferable to Rec. 43 of the Botanical Rules to govern bacteriological practice. This reads as follows: "While specific substantive names derived from names of persons may be written with a capital initial letter, all other specific names are to be written with a small initial letter. Some examples taken from bacteriological literature are: *Salmonella Schottmuelleri* or *Salmonella schottmuelleri*, *Bacillus Welchii* or *Bacillus welchii*, *Acetobacter Pasteurianum* or *Acetobacter pasteurianum*, *Corynebacterium ovis*, *Nitrosomonas javanensis*, *Rhizobium japonicum*."

In the MANUAL all species names are written with a small letter. It is felt that the value of a name as a name is lessened if capitals or other marks are used to indicate etymology. The derivation of generic and specific names is given separately in the descriptive material.

Likewise for obvious reasons, microbiologists refused (Jour. Bact., 33, 1937, 445) to follow the botanical and zoological practice which permits the use of duplicate generic names, one for an animal and the other for a plant group; and accepted the following rules to govern their practice.

"a. Generic homonyms are not permitted in the group *Protista*

b. It is advisable to avoid homonyms amongst *Protista* on the one hand, a plant or animal on the other."

The following actions of the International Committee on Bacteriological Nomenclature (Cent. f. Bact., II Abt., 92, 1935, 481) were confirmed (Jour. Bact., 33, 1937, 445).

*Bacillus* Cohn 1872 was accepted as a *genus conservandum* with *Bacillus subtilis* Cohn *emend.* Prazmowski 1880 as type species. It was agreed that *Bacillus* should be defined so as to exclude bacterial species which do not form endospores; and that the so-called Marburg strain found in type culture collections should be accepted as the type or standard strain.

At the Third International Congress of Microbiology held in New York City in September, 1939, a series of recommendations of the Permanent International Committees on Bacteriological Nomenclature were accepted at the plenary session of the Congress. The third and fourth recommendations were:

3. That the Nomenclature Committee, as at present constituted, shall continue to function under the auspices of the International Association of Microbiologists as it did under the International Society for Microbiology.

4. That the International Committee shall select from its membership a Judicial Commission consisting of twelve members, exclusive of members *ex officio*, and shall designate a Chairman from the membership of the Commission. The two Permanent Secretaries of the International Committee on Bacteriological Nomenclature shall be members *ex officio* of the Judicial Commission. The Commissioners shall serve in three classes of four commissioners each for nine years, so that one class of four commissioners shall retire at every International Congress. In case of the resignation or death of any Commissioner, his place shall be filled for the unexpired term by the International Committee at its next meeting.

By prompt action at and subsequent to the Congress ballots were cast in spite of war conditions by 26 of the 62 members of the Permanent Committee on Nomenclature. These ballots when examined by the joint Secretaries of the Permanent Committee in November, 1942 were found to have resulted in the selection of the persons whose names appear below. These

are grouped in the three classes specified by the Permanent Committee, those receiving the highest number of votes being placed in the nine year class, those receiving the next highest in the six year class, etc. Names in the classes are arranged alphabetically.

*Elected for nine years.*—(The term normally expires in 1948.) R. E. Buchanan (U.S.A.), A. J. Kluyver (The Netherlands), E. G. D. Murray (Canada), S. Orla Jensen (Denmark); *Elected for six years.*—(Term normally expires in 1945.) J. Howard Brown (U.S.A.), A.-R. Prévot (France), J. Ramsbottom (Great Britain), Th. Thjøtta (Norway); *Elected for three years.*—(Term normally would have expired in 1942) A. Lwoff (France), R. Renaux (Belgium), A. Sordelli (Argentina), C. Stapp (Germany).

This announcement was made (Sci., 97, 1943, 370) in the hope that some plan for taking tentative action on questions of nomenclature could be developed by those members of the Commission who could be reached under war conditions.

While no provision was made in 1939 for the contingencies that have arisen, it is felt that those elected should serve until successors are elected. Professor R. E. Buchanan has been asked to act as Chairman *pro tem* of the Judicial Commission as there is no possibility of securing an election under the rules as adopted.

Tentative International Rules of Bacteriological Nomenclature were presented to the Third International Congress of Microbiology by a U.S.A.-Canadian Committee on Compilation of Proposals on Bacteriological Nomenclature. As it proved impossible to give adequate consideration to these proposals during the Congress, the following recommendations of the Permanent Committee on Nomenclature were accepted:

1. That a recognized Bacteriological Code be developed.
2. That publication of such a proposed Code, when developed, be authorized with the proviso that it shall be regarded as wholly tentative, but in the hope that it shall be widely tested so that it may be brought up for further consideration and final disposition at the next Microbiological Congress which should normally take place in 1942.

Copies of this tentative Code have been issued in mimeographed form by Prof. R. E. Buchanan, Iowa State College, Ames, Iowa, U.S.A., Chairman of the U.S.A.-Canadian Committee and may be obtained from him.

## CLASS SCHIZOMYCETES NÄGELI

(Bericht Verhandl. d. bot. Section d. 33 Versammlung deutsch. Naturforsch. u. Arzt. Bot. Ztg., 1857, 760 )

Synonyms: *Bacteria* Cohn, Beitr. Biol. d. Pflanzen, 1, Heft 1, 1872, 136; *Bacteriaceae* Cohn, *ibid.*, 237; *Bacteriales* Clements (as an ordinal name), The Genera of Fungi, Minneapolis, 1909, 8, *Schizomycetaceae* De Toni and Trevisan, in Saccardo, Sylloge Fungorum, 8, 1889, 923; *Schizomycetacea* Castellani and Chalmers, Manual of Tropical Medicine, 3rd ed., 1919, 924, *Mychota* Enderlein, Bakteriencyclogenie, 1924, 236; *Schizomycetae* Stanier and Van Niel, Jour. Bact., 42, 1941, 458.

Typically unicellular plants. Cells usually small, sometimes ultramicroscopic. Frequently motile. As in the closely related blue-green algae (Class *Schizophyceae*), the cells lack the definitely organized nucleus found in the cells of higher plants and animals. However, bodies containing chromatin which may represent simple nuclei are demonstrable in some cases. Individual cells may be spherical; or straight, curved or spiral rods. These cells may occur in regular or irregular masses or even in cysts. Where they remain attached to each other after cell division, they may form chains or even definite filaments. The latter may show some differentiation into holdfast cells, and into motile or non-motile reproductive cells (conidia). Some grow as branching mycelial threads whose diameter is not greater than that of ordinary bacterial cells, i.e., about one micron. Some species produce pigments. The true purple and green bacteria possess pigments much like or related to the true chlorophylls of higher plants. These pigments have photosynthetic properties. The phycocyanin found in the blue green algae does not occur in the *Schizomycetes*. Multiplication is typically by cell division. Endospores are formed by some species included in *Eubacteriales*. Sporocysts are found in *Myxobacteriales*. Ultramicroscopic reproductive bodies are found in *Borrelomycetaceae*. The bacteria are free-living, saprophytic, parasitic or even pathogenic. The latter types cause diseases of either plants or animals. Seven orders are recognized.

### Key to the Orders and Sub-Orders of the Class Schizomycetes.

- A. Cells rigid, not flexuous. Motility by means of flagella or by a gliding movement.  
 1. Cells single, in chains or masses. Not branching and mycelial in character. Not arranged in filaments. Not acid-fast. Motility when present by means of flagella.

#### Order I. *Eubacteriales*, p. 66.

- a. Do not possess photosynthetic pigments. Cells do not contain free sulfur.  
 b. Not attached by a stalk. Do not deposit ferric hydroxide.

##### Sub-Order I. *Eubacteriineae*, p. 67.

- bb. Attached to substrate, usually by a stalk. Some deposit ferric hydroxide.

##### Sub-Order II. *Caulobacteriineae*, p. 827.

- aa. Possesses photosynthetic chlorophyll-like pigments. Some cells contain free sulfur.

##### Sub-Order III. *Rhodobacteriineae*, p. 838.

2. Organisms forming elongated usually branching and mycelial cells. Multiply by cell division, special spores, oidiospores and conidia. Sometimes acid-fast. Non-motile.

Order II. *Actinomycetales*, p. 895.

3. Cells in filaments frequently enclosed in a tubular sheath with or without a deposit of ferric hydroxide. Sometimes attached. Motile flagellate and non-motile conidia. Filaments sometimes motile with a gliding movement. Cells sometimes contain free sulfur.

Order III. *Chlamydo bacteriales*, p. 981.

B. Cells flexuous, not rigid.

1. Cells elongate. Motility, by creeping on substrate

Order IV. *Myzobacteriales*, p. 1005.

2. Cells spiral. Motility, free swimming by flexion of cells.

Order V. *Spirochaetales*, p. 1051.

Supplements. Groups whose relationships are uncertain.

1. Obligate intracellular parasites or dependent directly on living cells.
  - a. Not ultramicroscopic and only rarely filterable. More than 0.1 micron in diameter.

Group I. Order *Rickettsiales*, p. 1083.

- aa. Usually ultramicroscopic and filterable. Except for certain pox viruses of animals and a few plant viruses, less than 0.1 micron in diameter.

Group II. Order *Virales*, p. 1128.

2. Grow in cell-free culture media with the development of polymorphic structures including rings, globules, filaments and minute reproductive bodies (less than 0.3 micron in diameter).

Group III. Family *Borrelomycetaceae*, p. 1201.

## ORDER I. EUBACTERIALES BUCHANAN.

(Jour. Bact., 2, 1917, 162.)

Simple and undifferentiated rigid cells which are either spherical or rod-shaped. The rods may be short or long, straight or curved or spiral. Some groups or species are non-motile, others show locomotion by means of flagella. Elongated cells divide by transverse fission and may remain attached to each other in chains. Spherical organisms divide either by parallel fission producing chains, or by fission alternating in two or three planes producing thus either tetrads or cubes of 8 and multiples of 8 cells. Many spherical cells form irregular masses in which the plane of division cannot be ascertained. Endospores occur in some species. Some species are chromogenic, but only in a few is the pigment photosynthetic (bacteriochlorophyll or other chlorophyll-like pigments).

A group of rather large, spherical to short rod-shaped, colorless sulfur bacteria, which some feel should be included in the order *Eubacteriales*, has been attached as an Appendix to the order *Chlamydo bacteriales* on account of the physiological similarity between the former organisms and the *Beggiatoaceae*. These are in Family *Achromatiaceae*, p. 997.

SUB-ORDER I Eubacteriineae BREED, MURRAY AND HITCHENS.  
(Jour. Bact., 47, 1944, 421.)

These are, as the name *Eubacteriineae* implies, the true bacteria in the narrower sense of the word. The cells are rigid and free. Branching occurs only under abnormal conditions of life. They are not attached by holdfasts nor stalks. They form no sheaths. One-third of the species form pigments, but these have no photosynthetic properties. Endospores occur in one family (*Bacillaceae*), rarely in others.

Key to the Families of the Sub-Order Eubacteriineae.

I. No endospores (except *Sporosarcina*)

A. Can develop on inorganic media. Autotrophic and facultative autotrophic.  
Family I. *Nitrobacteriaceae*, p. 69

B. Cannot develop on inorganic media (exceptions, see Family XII *Bacteriaceae*).  
Heterotrophic

1. Polar flagellate, straight, curved or spiral rods. Gram-negative. (Some species with a single flagellum will be found under Family IV *Rhizobiaceae*, Family V *Micrococcaceae* and Family VIII *Corynebacteriaceae*).  
Family II. *Pseudomonadaceae*, p. 82

2. Large, oval, pleomorphic cells sometimes almost yeast-like in appearance. Free living in soil. Fix free nitrogen. Peritrichous flagellation.  
Family III. *Azotobacteriaceae*, p. 219

3. Peritrichous or non-motile rods, and cocci.

a. Heterotrophic rods which may not require organic nitrogen for growth. Usually motile with one to six or more flagella. Usually form nodules or tubercles on roots of plants, or show violet chromogenesis.  
Family IV. *Rhizobiaceae*, p. 223

aa. Heterotrophic rods or cocci which utilize organic nitrogen and usually carbohydrates

b. Spherical cells in masses, tetrads, and packets. A few species are motile with one or two flagella.

c. Gram-positive to Gram-negative cocci. Not obligate parasites.

Family V. *Micrococcaceae*, p. 235.

cc. Gram-negative, and sometimes anaerobic cocci. Obligate parasites

Family VI. *Neisseriaceae*, p. 295.

bb. Spherical cells which grow in pairs and chains, and rods

c. Gram-positive cocci and rods. Non motile (some species of *Streptococcaceae* or *Corynebacteriaceae* may show motility).

d. Microaerophilic to anaerobic cocci and rods. Frequently in chains. Active in the fermentation of sugars. Never reduce nitrates

Family VII. *Lactobacteriaceae*, p. 305.

dd. Usually aerobic, but sometimes anaerobic rods. Less active in the fermentation of sugars. May or may not reduce nitrates.

Family VIII. *Corynebacteriaceae*, p. 381

cc. Gram-negative rods. When motile, from four to many peritrichous flagella.

d. Grow well on ordinary media containing peptone. Aerobic to facultative anaerobic.

e. Gram-negative, straight rods which ferment sugars with the formation of organic acids.

f. Produce little or no acid in litmus milk. May or may not reduce nitrates. Many yellow chromogens. Borderline between this and following family indistinct. Some species anaerobic.

Family IX. *Achromobacteriaceae*, p. 412.

ff. Produce  $\text{CO}_2$  and frequently visible gas ( $\text{CO}_2 + \text{H}_2$ ) from glucose. Reduce nitrates. Usually from the alimentary, respiratory or urinary tract of vertebrates, though some are free-living or even plant parasites.

Family X. *Enterobacteriaceae*, p. 443.

dd. Small Gram-negative rods. Obligate parasites which usually require body fluids for growth. Do not grow well on ordinary media. Some are anaerobic.

Family XI. *Parabacteriaceae*, p. 545.

ccc. Rods of varied types not included in above families. Aerobic to facultative anaerobic.

Family XII. *Bacteriaceae*, p. 596.

II Form endospores. Large rods, sometimes in chains. Aerobic to anaerobic.

Family XIII. *Bacillaceae*, p. 704.

## \*FAMILY I. NITROBACTERIACEAE BUCHANAN

(Jour. Bact., 2, 1917, 319 and Jour. Bact., 3, 1918, 179.)

Cells without endospores. Rod-shaped or ellipsoidal except for one spherical species (*Nitrosococcus nitrosus*) Spiral rods in *Nitrospirilla* and in one species of *Thiobacillus*. Flagella either polar (so far as known), or absent. Gram stain uncertain, but presumably Gram-negative for all of the polar flagellate, rod-shaped species except for *Nitrosomonas monocella* which is reported to be Gram-positive. Capable of growing without organic compounds, using CO<sub>2</sub> as the source of carbon, and obtaining their energy by oxidation of ammonia, nitrite, hydrogen, sulfur, or thiosulfate. Some species can also utilize organic compounds. Non-parasitic, usually soil or water forms

### Key to the tribes and genera of family Nitrobacteriaceae.

- A. Organisms oxidize ammonia to nitrite, or nitrite to nitrate. Growth on standard media very poor or absent.

#### Tribe I. *Nitrobacteriaceae*, p. 70.

- a. Cells oxidize ammonia to nitrite

- b. Cells are separate, free or in dense aggregates Do not form zoogloea.

- c. Cells ellipsoidal

Genus I. *Nitrosomonas*, p. 70.

- cc. Cells spherical.

Genus II. *Nitrosococcus*, p. 71.

- ccc. Cells spiral.

Genus III. *Nitrospirilla*, p. 71.

- bb. Cells form a zoogloea

- c. The zoogloea is surrounded by a common membrane forming a cyst.

Genus IV. *Nitrocyctis*, p. 72.

- cc. The massed cells are embedded in slime. No common membrane surrounds the cells

Genus V. *Nitrozoogloea*, p. 73.

- aa. Cells oxidize nitrite to nitrate

- b. Cells form no zoogloea

Genus VI. *Nitrobacter*, p. 74.

- bb. Cells form a zoogloea

Genus VII. *Nitrocyctis*, p. 75

- B. Organisms oxidize hydrogen.

#### Tribe II. *Hydrogenomonadaceae*, p. 76

- a. Aerobic, non-spore forming rods with single polar flagellum, or non-motile

Genus I. *Hydrogenomonas*, p. 76

---

\* Text revised by Prof. H. S. Breed and Prof. H. J. Conn, Geneva, N. Y., Dec., 1927. Completely revised by Dr. R. L. Starkey, New Jersey Agricultural Experiment Station, New Brunswick, N. J., March, 1941

C. Organisms oxidize sulfur or thiosulfate and similar inorganic compounds of sulfur.

Tribe III. *Thiobacilleae*, p. 78.

- a. Aerobic to anaerobic, non-spore-forming rods with a single polar flagellum on each (so far as known), or non-motile.

Genus I. *Thiobacillus*, p. 78.

TRIBE I. NITROBACTERIEAE WINSLOW ET AL.

(Jour. Bact., 5, 1920, 201.)

Organisms deriving energy from the oxidation of ammonia to nitrite or from nitrite to nitrate and depend on this oxidation for growth. Fail to grow on media containing organic matter in the absence of the specific inorganic materials used as sources of energy. Many organic compounds commonly used in standard culture media are toxic to this group.

Genus I. *Nitrosomonas* Winogradsky.

(*Nitromonas* Winogradsky, Ann. Inst. Past., 4, 1890, 257; Arch. Sci. biol., St. Petersburg, 1, 1892, 127; *emend.* S. and H. Winogradsky, Ann. Inst. Past. 50, 1933, 350)

Cells ellipsoidal, non-motile or with a single polar flagellum, occurring singly, in pairs, short chains or irregular masses, which are not enclosed in a common membrane. Oxidize ammonia to nitrite more rapidly than the other genera of this tribe. From Latin, *nitrosus*, full of soda; M.L. *nitrous*; and Greek *monas*, a unit; M.L. a monad.

The type species is *Nitrosomonas europaea* Winogradsky.

1. *Nitrosomonas europaea* Winogradsky. (Arch. Sci. biol., St. Petersburg, 1, 1892, 127; *Bacterium nitrosomonas* Lehmann and Neumann, Bakt. Diag., 2nd ed., 2, 1899, 187; *Pseudomonas europaea* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 29; *Planococcus europaeus* Vuillemin, Ann. Mycologie, Berlin, 11, 1913, 525.) From Latin, *europaeus*, of Europe.

Rods: 0.9 to 1.0 by 1.1 to 1.8 microns occurring singly, rarely in chains of three to four. Possess a single polar flagellum 3 to 4 times the length of the rods, or rarely one at either end.

Grow readily in aqueous media without organic matter, and containing ammonium sulfate, potassium phosphate, and magnesium carbonate. The cells accumulate in soft masses around the particles of magnesium carbonate at the bottom of the flask. The liquid is occasionally turbid through development of motile swarmer cells or monads.

Small, compact, sharply defined colonies brownish in color on silica gel.

Aerobic.

Strictly autotrophic.

Source: Soils of Zurich, Switzerland; of Gennevilliers, France; and Kazan, Russia.

Habitat: Presumably widely distributed in soil.

1a. *Nitrosomonas europaea* var. *italica* Perotti (Rendic. d. Accad. d. Lincei Roma, 15, 1906, 516; Abs. in Cent. f. Bakt., II Abt., 19, 1907, 337). Also see Engel and Skallau (Cent. f. Bakt., II Abt., 97, 305, 1937).

2. *Nitrosomonas monocella* Nelson. (Cent. f. Bakt., II Abt., 83, 1931, 287.) From Greek *monos*, single and Latin *cella*, room; M.L. single cell.

Ovoid rods: 0.6 to 0.9 micron, often occurring in pairs. Young cells nearly spherical. Motile by means of a single

polar flagellum 3 to 5 times as long as the rod. Gram-positive (Nelson) Found negative by H. J. Conn (personal communication).

No growth in nutrient broth, nutrient agar, nutrient or plain gelatin, plain or litmus milk, glucose or plain yeast water, or on potato.

Silica gel or agar plates of inorganic medium: No typical colonies, but yellowish brown masses of growth around particles of  $\text{CaCO}_3$  in the medium

Inorganic liquid medium containing ammonium salts: Uniform development throughout the liquid as well as in the carbonate sediment.

Even low concentrations of organic matter retard or completely inhibit the initiation of growth. Plant extracts are toxic.

Free  $\text{CO}_2$  and  $\text{O}_2$  necessary for growth. Optimum pH 8.0 to 9.0. Poor growth below pH 7.0. Some growth above pH 9.0.

Optimum temperature for growth and oxidation  $28^\circ\text{C}$ .

Aerobic.

Strictly autotrophic.

Source: Isolated from field soil.

Habitat: Presumably widely distributed in soil.

S Winogradsky and H. Winogradsky (Ann. Inst. Pasteur, 50, 1933, 391) have described 5 cultures of *Nitrosomonas* which were obtained from soils of France. An additional culture has been described by H. Winogradsky (Ann. Inst. Pasteur, 58, 1937, 394) from activated sludge.

### Genus II *Nitrosococcus* Winogradsky.

(Arch. Sci. biol., St. Petersburg, 1, 1892, 127.)

..... *Oxidize ammonia to nitrite.*  
..... *coccus.*

1. *Nitrosococcus nitrosus* (Migula) Bergey et al. (*Nitrosococcus* Winogradsky, Ann. Inst. Pasteur, 5, 1891, 577, Arch. Sci. biol., St. Petersburg, 1, 1892, 127; *Micrococcus nitrosus* Migula, Syst. d. Bakt., 2, 1900, 191; *Nitrosococcus americanus* Buchanan, Jour. Bact., 3, 1918, 180; Manual, 2nd ed., 1923, 35) From Latin, *nitrosus*, full of soda; M.L. *nitrosus*

Large spheres, 15 to 17 microns in size, with thick cell membrane. Motility could not be demonstrated. Stains readily with aniline dyes. Observed no zoogloea formation. Gram-positive

(Omehanski, Cent. I. Bakt., II Abt., 19, 1907, 263)

Liquid medium Turbidity

Silica gel: Both dark and light colonies. Surface colonies look like small drops of a turbid yellowish liquid.

Aerobic.

Optimum temperature  $20^\circ$  to  $25^\circ\text{C}$ .

Source: Isolated from soil from Quito, Ecuador; Companias, Brazil, Melbourne, Australia.

Habitat: Presumably widely distributed in soil

### Genus III. *Nitrospira* Winogradsky.

(Compt. rend. Acad. Sci., Paris, 192, 1931, 1034; Ann. Inst. Pasteur, 59, 1933, 401.)

Cells spiral-shaped. Oxidize ammonia to nitrite very slowly. From Latin, *nitrosus*, full of soda; and *spira*, coil, spiral; M.L. *nitrosus spiralis*.

The type species is *Nitrospira briensis* Winogradsky.

1. *Nitrosospira briensis* Winogradsky (Ann. Inst. Pasteur, 50, 1933, 407.) From French, *Brie*, a place name; M.L. of *Brie*.

Spirals wound tightly to form very small cylinders as long as 15 to 20 microns. Short spirals have the appearance of short rods and ellipsoidal cells. Small pseudo-cocci were observed in old cultures.

Colonies on silica gel: Small colonies which occasionally contain cyst-like aggregates of cells. The cysts are more poorly developed than in *Nitrosocystis*.

Aerobic.

Reaction optimum: pH 7.0 to 7.2.

Source: Uncultivated pasture soil of Brie, France.

Habitat: Presumably widely distributed in soil.

2. *Nitrosospira antarctica* Winogradsky. (Ann. Inst. Pasteur, 50, 1933, 407.) From Greek, *antarkitos*, southern, antarctic.

Cells and colonies similar to *N. briensis* except that the cells are generally wound together to form more compact spirals.

Aerobic.

Reaction optimum: pH 7.0 to 7.2

Source: Soil from the Antarctic.

Habitat: Presumably widely distributed in soil.

#### Genus IV. *Nitrosocystis* Winogradsky.

(Compt. rend. Acad. Sci., Paris, 192, 1931, 1003; Ann. Inst. Pasteur, 50, 1933, 399.)

Cells ellipsoidal or elongated, uniting in compact, rounded aggregates surrounded by a common membrane to form cysts. The cysts disintegrate to free the cells, particularly when transferred to fresh media. Within the cyst, the cells are embedded in slime. Oxidize ammonia to nitrite at a rate intermediate between *Nitrosomonas* and *Nitrosospira*. From Latin, *nitrosus*, full of soda; and Greek, *kystis*, bladder; M.L. nitrous cyst.

The type species is *Nitrosocystis javanensis* comb. nov.

1 *Nitrosocystis javanensis* comb. nov. (*Nitrosomonas javanensis* Winogradsky, Arch. Sci. biol., St. Petersburg, 1, 1892, 127, *Pseudomonas javanensis* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 30, Compt. rend. Acad. Sci., Paris, 192, 1931, 1003.) From Latin, of Java.

Small ellipsoidal cells having a diameter of 0.5 to 0.6 micron. Possess a polar flagellum 20 times as long as the rods.

In liquid medium produces very compact zoogloal masses of cells and motile swimmers. The large zoogloea are themselves composed of smaller compact aggregates of cells.

On silica gel the colonies are circular to elliptical becoming clear or light brown.

Aerobic.

Strictly autotrophic.

Source: Soil of Buitenzorg, Java; Tokyo, Japan; La Reghaia, Tunisia.

Habitat: Presumably widely distributed in soil.

2. *Nitrosocystis coccoides* nom. nov. (*Nitrosocystis a*, S Winogradsky and H. Winogradsky, Ann. Inst. Pasteur, 50, 1933, 401.) From Greek, *kokkos*, a grain; *eidos*, form, shape; M.L. coccus-like.

Ellipsoidal cells about 1.5 microns in diameter. Occur as compact aggregates of cells imbedded in mucus and surrounded by a thickened capsule to form cyst-like bodies. Cells rarely solitary but more often in pairs and in small groups of four or more. Probably motile. The mucus which surrounds the cells is not readily stained, whereas the outside coating stains more easily.

Colonies on silica gel: As colonies develop, the coating of CaCO<sub>3</sub> on the gel becomes yellowish and dissolves and the

colony appears as a bulbous, angular, brown body which may become 0.5 mm in diameter. The cells are held firmly together in these irregularly shaped bulbous aggregates.

Aerobic.

Source: Poor soils of Brie and elsewhere in France.

Habitat: Presumably widely distributed in forest and manured soils

A similar culture called *Nitrosocystis* B.A. was isolated from activated sludge by H. Winogradsky (Compt. rend. Acad. Sci., Paris, 200, 1935, 1888; Ann. Inst. Pasteur, 58, 1937, 326). It produced compact, bulbous, dented cyst-like aggregates of cells having a yellow color. The colonies produced clear zones on silica gel coated with  $\text{CaCO}_3$ . These cysts were composed of oval or elongated coccoid cells imbedded in mucus and surrounded by a thickened capsule, com-

posed of two layers. The cells become dispersed from the cysts as motile cells and form new colonies. This culture differs from *N. coccoides* in that the colonies have a pale reddish yellow color and the oval cells are 0.5 by 1.5 microns in size.

Cultures of *Nitrosocystis* were obtained by Rommell (Svensk. botan. Tidskrift, 28, 1932, 303) from forest soils. Kingma Boltjes (Arch. f. Mikrobiol., 6, 1935, 79) obtained cultures which produced masses of cells, some of which were loose and others compact. They were not believed to be true zoogloea since no capsule or slimy substance was noted. The development of true cysts by nitrifying bacteria was questioned. Winogradsky (Bull. d. l'Inst. Pasteur, 33, 1935, 1074) concluded that Kingma Boltjes worked with a culture of *Nitrosocystis* and not of *Nitrosomonas* as was believed.

#### Genus V. *Nitrosogloea* H. Winogradsky.

(Compt. rend. Acad. Sci., Paris, 200, 1935, 1887; Ann. Inst. Pasteur, 58, 1937, 335.)

Cells ellipsoidal or rod-shaped. Embedded in slime to form zoogloea. No common membrane surrounds the cells aggregates. Oxidize ammonia to nitrite. From Latin, *nitrosus*, full of soda; and Greek, *gloea*, gluc, jelly; M.L. nitrous jelly.

The type species is *Nitrosogloea merismoides* H. Winogradsky.

1. *Nitrosogloea merismoides* H. Winogradsky. (*Nitrosocystis* "I", H. Winogradsky, Trans. Third Intern. Cong. Soil Sci., Oxford, 1, 1935, 139; Compt. rend. Acad. Sci., Paris, 200, 1935, 1887; Ann. Inst. Pasteur, 58, 1937, 333.) From Greek, *merismos*, a dividing, division; *eidos*, form, shape; M.L. division-like.

Ellipsoidal cells: 0.5 by 1.5 microns. Oval cells or short rods forming tetrads or chains, each group with its own sheath. The groups vary in shape to produce branched chains, irregular or compact aggregates.

Colonies on silica gel: Cells encased in a pale yellow mucilage giving the colony a dull appearance. Colony surface studded with little humps.

Aerobic.

Source: Activated sludge

Habitat: Unknown.

2. *Nitrosogloea schizobacteroides* H. Winogradsky. (*Nitrosocystis* "II", H. Winogradsky, Trans. Third Intern. Cong. Soil Sci., Oxford, 1, 1935, 139; Compt. rend. Acad. Sci., Paris, 200, 1935, 1887; Ann. Inst. Pasteur, 58, 1937, 333.) From Greek, *schizo*, to split; *bakterion*, a small rod; *eidos*, form, shape; M.L. like a dividing rod.

Rods: Elongated rods or short filaments 3 to 4 microns long.

Colonies on silica gel: Flat groups of cells are produced which are united in a common sheath. The aggregates form a

pseudo-tissue of interwoven filaments suggestive of a fungus pad. The pad can be removed as a unit from the medium.

Aerobic.

Source: Activated sludge.

Habitat: Unknown.

3. *Nitrosogloea membranacea* H. Winogradsky. (*Nitrosocystis* "III", H. Winogradsky, Trans. Third Intern. Cong. Soil Sci., Oxford, 1, 1935, 139; Compt. rend. Acad. Sci., Paris, 200, 1935, 1857; Ann. Inst. Pasteur, 68, 1937, 333.) From

Latin, *membranaceus*, of skin or membrane.

Ellipsoidal cells commonly in pairs and also solitary.

Colonies on silica gel: Appear as dull mucoid material with a pale straw color. The cells are held firmly together so that the entire colony is easily picked up with the transfer needle. No structural units within the colony.

Aerobic.

Source: Activated sludge.

Habitat: Unknown.

#### Genus VI. *Nitrobacter* Winogradsky.

(Winogradsky, Arch. Sci. biol., St. Petersburg, 1, 1892, 127; *Nitromonas* Orla-Jensen, Cent. f. Bakt., II Abt., 22, 1909, 331; not *Nitromonas* Winogradsky, Ann. Inst. Past., 4, 1890, 257; *Nitrobacterium* Castellani and Chalmers, Manual Trop. Med., 1919, 933.)

Cells rod-shaped. Oxidize nitrite to nitrate. From Latin, *nitrum*, soda; M.L. nitre; and Greek *baktron*, a small rod.

The type species is *Nitrobacter winogradskyi* Buchanan.

1. *Nitrobacter winogradskyi* Buchanan. (*Nitrobacter* Winogradsky, Arch. Sci. biol., St. Petersburg, 1, 1892, 127; *Bacterium nitrobacter* Lehmann and Neumann, Bakt. Diag., 2nd ed., 2, 1899, 187; *Bacillus nitrobacter* Löhnis, Vorlesungen landw. Bakt., Berlin, 1913, 152; Buchanan, Jour. Bact., 3, 1918, 180; *Nitrobacterium nitrobacter* Castellani and Chalmers, Manual Trop. Med., 1919, 933.) Named for S. Winogradsky, 1856- , the Russian microbiologist, who first isolated these bacteria.

Description taken from Gibbs, Soil Sci., 8, 1919, 448.

Short, non-motile rods with gelatinous membrane, 0.6 to 0.8 by 1.0 to 1.2 microns. Does not stain readily. Gram-negative (Omelianski, Cent. f. Bakt., II Abt., 19, 1907, 263.)

Can be cultivated on media free of organic matter. Sensitive to certain organic compounds.

Washed agar colonies. In 7 to 10 days very small, light brown, circular to irregular colonies, becoming darker.

Silica gel: Colonies smaller but more dense than on washed agar.

Washed agar slant: In 7 to 10 days scanty, grayish streak.

Inorganic solution medium: After 10 days flocculent sediment. Sensitive to ammonium salts under alkaline conditions.

Nitrite is oxidized to nitrate.

Aerobic.

Strictly autotrophic.

Optimum temperature 25° to 28°C.

Source: Soil.

Habitat: Presumably widely distributed in soil.

2. *Nitrobacter agilis* Nelson. (Cent. f. Bakt., II Abt., 83, 1931, 287.) From Latin *agilis*, quick, agile, motile.

Rods: 0.5 by 0.8 to 0.9 micron, occurring singly, sometimes in pairs or larger aggregates. Rapidly motile with a long, thin, polar flagellum often 7 to 10 times as long as the rod. (Non-motile culture obtained by Kingma Boltjes, Arch. f. Mikrobiol., 6, 1935, 79.) Gram-negative.

No growth in nutrient broth, nutrient agar, nutrient or plain gelatin, litmus or plain milk, glucose or plain yeast water, or on potato.

Nitrite agar: After two weeks, produces semi-spherical, minute, nearly transparent colonies. Oxidation usually complete in 10 to 14 days.

Inorganic liquid medium containing nitrite: Produces uniformly dispersed growth.

Optimum pH 7.6 to 8.6 Limits of growth 6.6 to 10.0.

Temperature relations: Optimum for growth 25° to 30°C. Optimum for oxidation 23°C. No oxidation at 37°C. Thermal death point 60°C. for five minutes.

Strictly autotrophic.

Aerobic.

Source: Isolated from greenhouse soils and from sewage effluents in Madison, Wisconsin.

Habitat: Presumably widely distributed in soil.

### Genus VII. *Nitrocystis* H. Winogradsky.

(Trans Third Intern. Cong Soil Sci., Oxford, 1, 1935, 139; *Nitrogloea* H. Winogradsky, Comp. rend. Acad. Sci., Paris, 200, 1935, 1888.)

Cells ellipsoidal or rod-shaped. Embedded in slime and united into compact zoogeal aggregates. Oxidize nitrite to nitrate. From Latin, *nitrum*, soda; M.L. *nitre*; and Greek, *kystis*, bladder, M.L. *nitric cyst*.

The type species is *Nitrocystis sarcinoides*.

1. *Nitrocystis sarcinoides* H. Winogradsky. (*Nitrocystis* B. A., Winogradsky, H., Compt. rend. Acad. Sci., Paris, 200, 1935, 1888; *Nitrocystis* "I" and "II", Winogradsky, H., Trans. Third Intern. Cong. Soil Sci., Oxford, 1, 1935, 139; Ann. Inst. Pasteur, 58, 1937, 336.) From Latin, *sarcina*, a packet; M.L. *Sarcina*, a genus; Greek, *eidos*, form, M.L. *Sarcina*-like.

Rods: Small rods 0.5 by 1.0 micron. Cells ellipsoidal or wedge-shaped and grouped in sarcina-like packets.

Colonies on silica gel: On the surface of gel coated with kaolin the colonies appear as small raised amber warts. The colonies grow up to 5 mm in diameter. The colonies are viscous and sticky when young and they become brown with age, shrink, and look like scales and become hard like grains of sand. Each colony is enveloped in several layers of a thick slime which holds the cells together so that the entire colony can be removed with a transfer needle.

Aerobic.

Source: Activated sludge.

Habitat: Unknown.

2. *Nitrocystis micropunctata* H. Winogradsky. (*Nitrocystis* "III", Winogradsky, H., Trans Third Intern. Cong. Soil Sci., Oxford, 1, 1935, 139; *Nitrogloea micropunctata* Winogradsky, H., Compt. rend. Acad. Sci., Paris, 200, 1935, 1888; Ann. Inst. Pasteur, 58, 1937, 326.) From Greek, *mikros*, small, little; and Latin, *punctatus*, spotted; M.L. with small spots.

Cells are ellipsoidal rods about 0.5 micron in diameter which stain poorly except at the ends. Encased in a viscous slime.

Colonies on silica gel: Like *N. sarcinoides* except that the colonies are more clear and they have a more plastic consistency. The cells are not held together by the slime in the colony as with *N. sarcinoides*. The capsule is more readily differentiated in old colonies.

Aerobic.

Source: Activated sludge.

Habitat: Unknown.

Appendix: The following have been placed in the Tribe *Nitrobacteriaceae*, sometimes incorrectly so:

*Bactoderma alba* Winogradsky. (Ann.

Inst. Pasteur, 50, 1933, 414) From soil. This is the type species of genus *Bacteroides* Winogradsky.

*Bacteroides rosea* Winogradsky (*loc. cit.*, p. 415). Isolated from soil.

*Bacterium nitrificans* Chester. (Nitratbildner aus Northeim, Burri and Stutzer, *Cent. f. Bakt.*, II Abt., 1, 1895, 735; Chester, *Ann. Rept. Del. Col. Agr. Exp. Sta.*, 9, 1897, 94, *Bacillus nitrificans* Chester *Man. Determ. Bact.*, 1901, 239; *Achromobacter nitrificans* Bergey et al., *Manual*, 1st ed., 1923, 137.) From soil. Description of this organism was shown by Winogradsky (*Cent. f. Bakt.*, II Abt., 2, 1896, 415 and 449) to have been based on impure cultures.

*Microderma minutissima* Winogradsky. From soil. This is the type species of genus *Microderma* Winogradsky.

*Microderma vacuolata* Winogradsky (*loc. cit.*). Isolated from soil.

*Nitrosobacillus thermophilus* Campbell. See *Bacillus* appendix.

*Nitrobacter flavum* Sack. (*Cent. f. Bakt.*, II Abt., 62, 1924, 20) Isolated from garden earth. See description,

*Manual*, 5th ed., 1939, 74. Heterotrophic and does not belong here (Kingma Boltjes, *Arch. f. Mikrobiol.*, 6, 1935, 83).

*Nitrobacter oligotrophum* Beijerinck. (*Folia Microbiol.*, 3, 1914, 91; *Verzamelde Geschriften van M. W. Beijerinck*, 5, 1922, 190.) Isolated from soil. On cultivation this species lost its autotrophic habit and became heterotrophic. The organism was then called *Nitrobacter polytrophum* Beijerinck.

*Nitrobacter opacum* Sack (*loc. cit.* p. 21). Source and relationships as above. See *Manual*, 5th ed., 1939, 75.

*Nitrobacter punctatum* Sack (*loc. cit.*, p. 20). Source and relationships as above. See *Manual*, 5th ed., 1939, 75.

*Nitrobacter roseo-album* Sack (*loc. cit.*, p. 17; *Serratia roseo-alba* Bergey et al., *Manual*, 3rd ed., 1930, 125.) Source and relationships as above. See description, *Manual*, 5th ed., 1939, 74.

*Nitrosomonas groningensis* Sack. (*Cent. f. Bakt.*, II Abt., 64, 1925, 34.) Source and relationships as above. See description, *Manual*, 5th ed., 1939, 77.

## TRIBE II. HYDROGENOMONADEAE PRIBRAM.

(*Jour. Bact.*, 18, 1929, 370.)

Short rods, non-motile or with lophotrichous flagella. Organisms capable of deriving energy from oxidation of hydrogen. They probably grow well on organic media without hydrogen, although this has not been shown to be true for all species.

### Genus I. *Hydrogenomonas* Orla-Jensen.\*

(*Cent. f. Bakt.*, II Abt., 22, 1909, 311.)

As the only genus of the tribe, its definition is identical with the definition of the tribe. From Greek *hydōr*, water; *genos*, producing and *monas*, a unit.

The type species is *Hydrogenomonas pantotropha* (Kaserer) Orla-Jensen.

\* This group of bacteria is characterized by the ability to grow in substrates containing no organic matter and to utilize elemental hydrogen as the source of energy for growth. Under these conditions CO<sub>2</sub> is used as the source of carbon. Bacteria with similar physiological characteristics but differing in morphology are placed in the genera *Bacterium*, *Bacillus* and *Clostridium*. Although other bacteria and even certain algae have enzyme systems which can activate hydrogen and reduce CO<sub>2</sub> in the process, there is no evidence that these organisms are able to grow in inorganic media.

*Key to the species of genus Hydrogenomonas.*

A. Not sensitive to high  $O_2$  concentrations Growth in solution media under autotrophic conditions characterized by turbidity without pellicle formation.

1 *Hydrogenomonas pantotropha*.

B. Sensitive to high  $O_2$  concentrations Growth in solution media under autotrophic conditions characterized by pellicle adhering to walls of container.

2 *Hydrogenomonas vitrea*

C. Sensitive to high  $O_2$  concentrations Growth in solution media under autotrophic conditions without pellicle formation.

3 *Hydrogenomonas flava*.

1. *Hydrogenomonas pantotropha* (Kaserer) Orla-Jensen (*Bacillus pantotrophus* Kaserer, Cent f Bakt., II Abt., 16, 1906, 688, Orla-Jensen, Cent f. Bakt., II Abt., 22, 1909, 311) From Greek *pantos*, everything and *trophos*, feeds on; M.L. omnivorous

Rods: 0.4 to 0.5 by 1.2 to 1.5 microns with rounded ends Occur singly, in pairs, and in chains. Encapsulated Actively motile by means of a single long polar flagellum. Gram stain not recorded. Bipolar staining in old cultures

Inorganic solution: When cultivated under an atmosphere of  $O_2$ ,  $CO_2$  and  $H_2$ , the liquid becomes turbid without pellicle formation

Inorganic solid media When cultivated under an atmosphere of  $O_2$ ,  $CO_2$  and  $H_2$ , the colonies are yellow and slimy, and the agar plates have an odor resembling hot soapy water.

Gelatin colonies: Yellow, smooth, rarely concentrically ringed or greenish

Gelatin stab. Growth only at surface As a rule no liquefaction.

Agar colonies Same as on gelatin, greenish, often slimy.

Broth: Turbid, somewhat slimy, and occasional pellicle

Milk: No coagulation. A yellow pellicle forms. Medium becomes slimy and assumes a dirty flesh color.

Potato: Moist, yellow, glistening.

Indole is not formed.

Hydrogen sulfide is not formed.

Nitrite is not produced from nitrate

Does not act on carbohydrates.

Aerobic.

Optimum temperature  $28^\circ$  to  $30^\circ C$ .

Facultative autotroph

Distinctive characters Develops autotrophically in inorganic medium under an atmosphere of  $H_2$ ,  $O_2$  and  $CO_2$ . Oxidizes hydrogen to water and uses  $CO_2$  as the source of carbon for growth.

Source. Isolated from soil near Vienna.

Habitat. Probably widely distributed in soil.

2 *Hydrogenomonas vitrea* Niklenski. (Jahrb. f. wissensch. Botanik, 48, 1910, 113) From Latin *vitreus*, of glass, transparent.

Rods 2.0 microns in length, cells adhering to each other as by slime Motility not observed

Agar colonies on inorganic medium in presence of  $H_2$ ,  $O_2$  and  $CO_2$ . Delicate, transparent, with slight fluorescence, and yellow center. Surface folded. Do not develop readily beneath the surface of medium

Agar streak on inorganic substrate. Same as agar colonies except that growth is spreading.

Inorganic liquid medium in presence of  $H_2$ ,  $O_2$  and  $CO_2$ . Pellicle, adherent to wall of tube. Good development when there is from 2 to 5 per cent oxygen in the gas At higher  $O_2$  concentrations good growth occurs only in association with *H. flava* or other bacteria.

Oxidizes hydrogen to water.

Microaerophilic, growing in an atmosphere of low oxygen tension, not exceeding 8 per cent.

Facultative autotroph.

Distinctive characters: Grows in substrates containing no organic matter and produces a pellicle.

Source: Isolated from mud, garden soil, pasture land, vegetable mold, and peat.

Habitat: Presumably widely distributed in soil.

3. *Hydrogenomonas flava* Niklewski. (Jahrb. f. wissenschaft. Botanik., 48, 1910, 113; emend. Kluyver and Manten, Antonie v. Leeuwenhoek, 8, 1942, 71.) From Latin *flavus*, yellow.

Rods: 1.5 microns in length. Motility by polar flagella. Gram-negative.

Agar colonies on inorganic medium in presence of  $H_2$ ,  $O_2$  and  $CO_2$ : Small, smooth, yellow, shining, adhering to medium. Develop well below surface of medium, but growth is paler.

Gelatin not liquefied.

Inorganic liquid medium in presence of  $H_2$ ,  $O_2$ , and  $CO_2$ : No pellicle formation. Good development when there is from 2 to 8 per cent oxygen in the gas. At higher  $O_2$  concentrations good growth occurs

only in association with *H. vitrea* or other bacteria.

Oxidizes hydrogen to water.

Microaerophilic, growing in an atmosphere of low oxygen tension, not exceeding 8 per cent.

Facultative autotroph.

Distinctive characters: Found singly on slides whereas the rod-shaped cells of *Hydrogenomonas vitrea* tend to cling together in masses. Colonies on agar opaque, not transparent.

Source: Same as *H. vitrea*.

Habitat: Presumably widely distributed in soil.

Appendix: Incompletely described species are found in the literature as follows:

*Hydrogenomonas agilis* Niklewski. (Jubiläumsschrift f. Prof. E. Godlewski. Kosmos, Lemberg, 1913; See Cent. f. Bakt., II Abt., 40, 1914, 430.) From soil.

*Hydrogenomonas minor* Niklewski. (Jubiläumsschrift f. Prof. E. Godlewski. Kosmos, Lemberg, 1913; See Cent. f. Bakt., II Abt., 40, 1914, 431.) From soil.

### TRIBE III. THIOBACILLEAE BERGEY, BREED AND MURRAY.

(Preprint, Manual, 5th ed., Oct., 1933, v.)

Organisms capable of deriving their energy from oxidation of sulfur or sulfur compounds. Most species do not grow on organic media.

#### Genus I. *Thiobacillus* Beijerinck.

(Beijerinck, Cent. f. Bakt., II Abt., 11, 1904, 593; *Sulfomonas* Orla-Jensen, Cent. f. Bakt., II Abt., 22, 1909, 314; not *Thiobacillus* Ellis, Sulphur bacteria, London, 1932, 130; *Thiobacterium* Lehmann and Neumann, Bakt. Diag., 7 Aufl., 2, 1927, 517; not *Thiobacterium* Janke, Allgemeine Tech. Mikrobiol., 1, 1924, 68, Leipzig)

Small Gram-negative, rod-shaped cells. Non-motile or motile by means of a single polar flagellum. Derive their energy from the oxidation of incompletely oxidized sulfur compounds, principally from elemental sulfur and thiosulfate but in some cases also from sulfide, sulfite, and polythionates. The principal product of oxidation is sulfate, but sulfur is sometimes formed. They grow under acid or alkaline conditions and derive their carbon from carbon dioxide or from bicarbonates in solution; some are obligate and some facultative autotrophic. One species is facultative anaerobic. From Greek *theion*, sulfur and Latin *bacillus*, a small rod.

The type species is *Thiobacillus thioparus* Beijerinck.

*Key to the species of genus Thiobacillus.*

## I. Aerobic.

## A. Strictly autotrophic.

## 1. Optimum reaction for growth close to neutrality.

1. *Thiobacillus thioeparus*.

## 2. Optimum reaction for growth pH 2.0 to 3.5.

2. *Thiobacillus thiooxidans*.

## B. Facultative autotrophic.

3. *Thiobacillus novellus*.4. *Thiobacillus coproliticus*.

## II. Anaerobic in presence of nitrate.

5. *Thiobacillus denitrificans*.

1. *Thiobacillus thioeparus* Beijerinck (Cent. f. Bakt., II Abt., 11, 1904, 593; Nathanson, Mitt. Zool. Station Neapel, 15, 1902, 655; *Sulfomonas thioeparus* Orla-Jensen, Cent. f. Bakt., II Abt., 22, 1909, 326). From Greek *theion*, sulfur and *paro*, to make

Thin, short rods, 0.5 by 1 to 3.0 microns. Motile (non-motile culture reported. See Starkey, Soil Sci., 39, 1935, 197.) Gram-negative.

Thiosulfate medium (liquid): Pellicle consisting of cells and free sulfur.

Thiosulfate agar. Colonies small, circular, whitish yellow due to precipitated sulfur.

Optimum reaction: Close to neutrality.

Strictly autotrophic. Derives its energy by the oxidation of thiosulfate to sulfate and sulfur; also oxidizes sulfur to sulfate.

Aerobic.

Source: Sea water, river water, mud, sewage, and soil.

Habitat: Presumably widely distributed.

2. *Thiobacillus thiooxidans* Waksman and Joffe. (Jour. Bact., 7, 1922, 239, *Sulfomonas thiooxidans* Waksman, Jour. Bact., 7, 1922, 616; *Thiobacterium thiooxydans* Lehmann and Neumann, Bakt. Diag., 7 Aufl., 2, 1927, 517) From Greek *theion*, sulfur and *oxido*, to oxidize.

Short rods: 0.5 by 1.0 micron with rounded ends. Occur singly, in pairs, or in chains. Motile by means of a single

polar flagellum. Gram-negative (Starkey, Soil Sci., 39, 1935, 210).

Thiosulfate agar: Scant growth. Nearly transparent colonies.

Sulfur medium (liquid): Uniform turbidity. No sediment or surface growth. Medium becomes very acid (below pH 1.0).

Thiosulfate medium (liquid): Uniform turbidity. Medium becomes acid and sulfur is precipitated.

Nitrogen sources. Utilizes ammonia nitrogen but not nitrate nitrogen which is toxic. Asparagin, urea and peptone not utilized.

Temperature relations: Optimum 28° to 30°C. Slow growth at 18° and 37°C. Death occurs at 55° to 60°C.

Optimum reaction: pH 2.0-3.5. (Limiting reactions, pH 6.0 to less than pH 0.5.)

Strictly autotrophic, deriving its energy from the oxidation of elementary sulfur and thiosulfate, oxidizing these to sulfuric acid. It utilizes the CO<sub>2</sub> of the atmosphere as a source of carbon.

Strictly aerobic.

Distinctive characters: This species produces more acid, from oxidation of sulfur, and continues to live in a more acid medium, than any other living organism yet reported, the hydrogen-ion concentration of the medium increasing to a pH 0.6 and less.

Source: Isolated from composts of soil, sulfur, and rock phosphate and soils containing incompletely oxidized sulfur compounds.

Habitat: Soil.

3. *Thiobacillus novellus* Starkey. (Jour. Bact., 28, 1934, 365; Jour. Gen. Physiol., 18, 1935, 325; Soil Sci., 39, 1935, 207, 210.) From Latin *novellus*, new.

Short rods or ellipsoidal cells: 0.4 to 0.8 by 0.6 to 1.8 microns. Non-motile. Gram-negative.

Gelatin stab. Mucoid growth at point of inoculation. Sub-surface growth meager. Slow liquefaction.

Agar plate: Growth slow, colorless, moist, raised, circular, 1 mm in diameter. Deep colonies tiny, lens-shaped.

Thiosulfate agar plate: Growth slow, becoming white from precipitated sulfur. Surface colonies small, circular, moist. Crystals of  $\text{CaSO}_4$  appear throughout the agar.

Agar slant. Growth fairly abundant, soft, somewhat ropy, raised, shining, moderately spreading; whitish in reflected light, brownish opalescence in transmitted light.

Thiosulfate agar slant: Growth very thin, practically colorless. No sub-surface growth. Sulfur usually precipitated as white frosty film on the surface.

Agar stab. White to cream-colored growth confined close to point of inoculation. Penetrates to bottom of tube.

Thiosulfate agar stab. No appreciable surface growth.

Broth. Slightly turbid. Gelatinous pellicle. Forms long streamer-like network extending from surface to the bottom. Some sediment.

Thiosulfate solution medium: Uniform turbidity. No pellicle. Whitish sediment with thin incomplete membrane on the bottom of the flask. Reaction acid in a few days, changes pH 7.8 to 5.8 with decomposition of a small quantity of thiosulfate.

Sulfur solution medium of slightly alkaline reaction. No growth.

Potato slant. Growth limited, cream-colored, moist, shining, slightly brown.

Litmus milk. Slow development of slight alkalinity.

Facultative autotrophic.

Optimum reaction: Close to neutrality (limiting reactions pH 5.0 to 9.0).

Aerobic.

Distinctive characters: Oxidizes thiosulfate to sulfate and sulfuric acid. Does not oxidize free sulfur.

Source: Isolated from soils.

Habitat: Soils.

4. *Thiobacillus coproliticus* Lipman and McLees. (Soil Sci., 50, 1940, 432.) Latinized form of the English word *coprolite*, fossil dung.

Long thin rods: 0.1 to 0.2 by 6 to 8 (may measure 3 to 40) microns. Straight, S-shaped, and curved cells. Motile by means of a single polar flagellum.

Peptone soil extract agar: Slight growth.

Nutrient solution. Little or no growth.

Thiosulfate agar. Slow development. Produces small watery colonies raised above the agar surface. Colonies have been noted which were white from precipitated sulfur.

Thiosulfate solution: Thiosulfate is oxidized. Little or no turbidity. No pellicle. No sediment. Change in reaction from pH 7.6 to 6.1.

Sulfur medium: Sulfur is oxidized. No turbidity.

Facultative autotrophic.

Aerobic.

Distinctive characters: Develops in inorganic media and oxidizes thiosulfate and sulfur to sulfate. Media with slightly alkaline reactions most favorable for growth.

Source: Coprolite rock material from Triassic period (Arizona).

Habitat: Unknown.

5. *Thiobacillus denitrificans* Beijerinck. (Cent. f. Bakt., II Abt., 11, 1904, 597; *Sulfomonas denitrificans* Orla-Jensen, Cent. f. Bakt., II Abt., 22, 1909, 314.) From Latin, *de*, from; and M.L. *nitifico*, to nitrify.

Short rods, 0.5 by 1 to 3.0 microns long. Motile by means of a single polar flagel-

lum (Tjulpanova-Mossevitich, Arch. d. Sci. Biol., U.S.S.R., 50, 1930, 203).

Inorganic liquid medium: Growth with production of gas, predominantly nitrogen.

Thiosulfate agar medium: Colonies thin, clear, or weakly opalescent.

Optimum reaction: Neutral or slightly alkaline.

Autotrophic, utilizing carbon from  $\text{CO}_2$ , carbonates and bicarbonates. Considered to be strictly autotrophic by Lieske (Ber. d. deutsch. botan. Gesell., 50, 1912, 12.) and facultative by Tjulpanova-Mossevitich (*loc. cit.*). Beijerinck stated (Kon. Akad. v. Wetenschappen Amsterdam, 42, 1920, 899) that whereas the organism developed initially in an inorganic medium, it lost the autotrophic habit by cultivation in an organic medium.

Facultative anaerobic or even microaerophilic. Can live in the absence of free  $\text{O}_2$  in the presence of nitrate.

Distinctive characters. Oxidizes thiosulfate to sulfate under anaerobic conditions using nitrate as the hydrogen acceptor which is reduced to  $\text{N}_2$ . Also oxidizes sulfide, elemental sulfur, and dithionate.

Habitat: Canal and river water, salt water, soil, peat, composts and mud.

Appendix: The following species have been placed in *Thiobacillus* or are regarded as belonging to the genus:

*Thiobacillus concretivorus* Parker. (Austral. Jour. Exper. Biol. and Med. Sci., 23, 1915, 81) From corroded concrete sewers. Similar to or identical

with *Thiobacillus thiooxidans* Waksman and Joffe.

*Thiobacillus crenatus* Emoto. (Proc. Imp. Acad. Tokyo, 5, 1929, 149.) Isolated from mud of hot springs in Japan. See description, Manual, 5th ed., 1939, 84. Almost identical with *Thiobacillus thiooxidans* Waksman and Joffe.

*Thiobacillus lobatus* Emoto (*loc. cit.*, p. 148). Source and relationships as above. See description, Manual, 5th ed., 1939, 83.

*Thiobacillus thermitanus* Emoto (Bot. Mag. Tokyo, 42, 1928, 422.) Source and relationships as above. See description, Manual, 5th ed., 1939, 83.

*Thiobacillus trautweinii* Bergey et al. See *Flavobacterium* appendix.

*Thiobacillus umbonatus* Emoto (*loc. cit.*, p. 150). Source and relationships as above. See description, Manual, 5th ed., 1939, 84.

*Thiobacterium bejerinckii* Issatchenko and Salimonskaja (Zur Morphologie u. Physiologie der Thionsäurebakterien' (Russian with German abstract), Izvestia Gosud. Hidrobiol. Inst., No 21, 1928, 61.) From salt seas in Russia. Similar to or identical with *Thiobacillus thioparus* Beijerinck.

*Thiobacterium bejerinckii* var. *jacobsonii* Issatchenko and Salimonskaja (*loc. cit.*). Variety of previously mentioned species.

*Thiobacterium nathansonii* Issatchenko and Salimonskaja (*loc. cit.*). From salt seas in Russia. Similar to or identical with *Thiobacillus thioparus* Beijerinck.

## FAMILY II. PSEUDOMONADACEAE WINSLOW ET AL.

(Jour. Bact., 2, 1917, 555.)

Cells without endospores, elongate rods, straight or more or less spirally curved. One genus (*Mycoplana*) has branched cells. Usually motile by polar flagella which are either single or in small or large tufts. A few species are non-motile. Gram-negative (a few doubtful Gram-positive tests are recorded in *Pseudomonas*). Grow well and fairly rapidly on the surface of ordinary culture media excepting *Methanomonas* and some vibrios that attack cellulose. They are preferably aerobic, only certain vibrios including *Desulfovibrio* being anaerobic. Either water or soil forms, or plant or animal pathogens.

Key to the tribes of family Pseudomonadaceae.

## 1. Straight rods.

Tribe I. *Pseudomonadeae*, p. 82.

## 2. Cells more or less spirally curved.

Tribe II. *Spirilleae*, p. 192.

## TRIBE I. PSEUDOMONADEAE KLUYVER AND VAN NIEL.

(Cent. f. Bakt., II Abt., 94, 1936, 397.)

This tribe includes all of the straight and branching rods of the family.

Key to the genera of tribe Pseudomonadeae.

- I. Soil and water bacteria. Few animal and many plant pathogens. Usually produce a water-soluble pigment which diffuses through the medium as a bluish-green or yellowish-green pigment.

Genus I. *Pseudomonas*, p. 82.

- II. Cells usually monotrichous with yellow non-water-soluble pigment. Mostly plant pathogens causing necrosis.

Genus II. *Xanthomonas*, p. 150.

- III. Soil bacteria which oxidize methane.

Genus III. *Methanomonas*, p. 179.

- IV. Bacteria which oxidize alcohol to acetic acid.

Genus IV. *Acetobacter*, p. 179.

- V. Soil and water bacteria known to attack protamines.

Genus V. *Protaminobacter*, p. 189.

- VI. Soil bacteria with branching cells. Capable of using aromatic compounds, as phenol, etc., as a source of energy.

Genus VI. *Mycoplana*, p. 191.

Genus I. *Pseudomonas* Migula.\*

(Migula Arb. bakt. Inst. Karlsruhe, 1, 1894, 237; *Bacterium* Ehrenberg emend. Cohn, Beitr. z. Biol. d. Pflanzen, 1, Heft 1, 1872, 167; *Bactrillum* Fischer, Jahrb. f. wissensch. Bot., 27, 1895, 139; *Bactrinium* Fischer, *ibid.*, 41, *Arthrobactrinium* Fischer, *ibid.*, 139; *Arthrobactrillum* Fischer, *ibid.*, 139; *Bactrinus* Kendall, Public Health, 28, 1902, 484; *Bactrillus* Kendall, *ibid.*; *Bacterium* Ehrenberg emend. Smith, Bacteria

\* Revised for the 5th ed. of the Manual by Prof. D. H. Bergey, Philadelphia, Pennsylvania, 1937. Further revision for the 6th ed. by Prof. R. S. Breed, New York State Experiment Station, Geneva, New York, with incorporation of the plant pathogenic species by Prof. Walter H. Burkholder, Cornell University, Ithaca, New York, April, 1943.

in Relation to Plant Disease, 1, 1905, 171; *Denitromonas* Orla-Jensen, Cent. f. Bakt., II Abt., 22, 1909, 314; *Liquidomonas* Orla-Jensen, *ibid.*, 332; *Lamprella* Enderlein, Sitzber. Gesell. naturf. Freunde, Berlin, 1917, 317; *Fluoromonas* Orla-Jensen, Jour. Bact., 6, 1921, 271 )

Cells monotrichous, lophotrichous or non-motile. If pigments are produced, they are of greenish hue, fluorescent, and water-soluble.\* Gram-negative except Nos. 88, 122 and 123. Frequently ferment glucose, sometimes with the formation of visible gas. Inactive in the fermentation of lactose. Nitrates are frequently reduced either to nitrites or ammonia, or to free nitrogen. Some species split fat and attack hydrocarbons. Soil, water, and plant pathogens; very few animal pathogens. Certain salt water species (Nos. 53-64) some of which live in heavy brine are temporarily retained in this genus although they produce non-water-soluble pigments or phosphorescence. From *Gr. pseudos*, false, *monas*, a unit; *M. L. monad*.

The type species is *Pseudomonas aeruginosa* (Schroeter) Migula.

*Key to the species of genus Pseudomonas.*

- I. Soil and fresh water forms with a few that are pathogenic on cold or warm blooded animals.
  1. Green fluorescent pigment produced.
    - a. Gelatin liquefied.
    - b. Polar flagellate.
      - c. Grow readily at 37°C. Usually bluish-green.
        - 1 *Pseudomonas aeruginosa*.
        - 2 *Pseudomonas jaegeri*.
      - cc. Grow poorly or not at all at 37°C.
        - d. Milk not coagulated becoming alkaline
          - e. Soil and water organisms. Not known to digest cellulose.
            - 3 *Pseudomonas fluorescens*.
            - 4 *Pseudomonas viscosa*.
            - 5 *Pseudomonas fairmountensis*.
            - 6 *Pseudomonas urcae*.
            - 7 *Pseudomonas pavonacea*.
          - ee. Soil forms that attack cellulose.
            - 8 *Pseudomonas effusa*.
          - eee Pathogenic for lizards.
            - 9 *Pseudomonas reptilurous*.
          - dd. Milk unchanged becoming blue in association with lactic acid bacteria.
            10. *Pseudomonas syncyanea*.
        - ddd. Milk coagulated.
          11. *Pseudomonas schuylkilliensis*.
          12. *Pseudomonas chlororaphis*.
          - 13 *Pseudomonas myzogenes*.
          14. *Pseudomonas septica*.
        - dddd. Soil form. Action on milk not recorded
          15. *Pseudomonas boreopolis*.

\* See Tobie, Jour. Boet., 49, 1945, 459 for a discussion of the nature of these pigments.

I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1924, 86.)

**Etymology:** Greek *megalos*, large; *sporos*, seed, spore; large spored.

**Swarm stage (pseudoplasmodium):** Not described.

**Fruiting bodies:** About 80 to 160 microns wide, rounded, cushion-shaped, dark flesh color. Spores 2 microns

**Source and habitat:** Jahn (*loc. cit.*), on stag dung near Berlin.

**Illustrations:** Jahn (*loc. cit.*) Fig. Y, i to k, p. 87.

4. *Chondrococcus macrosporus* Krzemieniewski. (*Acta Soc. Bot. Poloniae*, 4, 1926). According to Krzemieniewski, not to be confused with Zukal's species, *Myxococcus macrosporus* (Ber. d. deutsch Bot. Gesellsch., 15, 1897, 542.)

**Etymology:** Greek *makros*, long, large; *sporos*, seed, spore; large-spored.

**Swarm stage (pseudoplasmodium):** Not described

**Fruiting bodies:** Much like *Chondrococcus coralloides*, differing in color and in size of spores. Spores 1.6 to 2.0 microns. Fruiting body yellow or light brown color, with long branches.

**Source and habitat:** Krzemieniewski (*loc. cit.*), found it first on leaves, later isolated from soil on rabbit dung.

**Illustrations:** Krzemieniewski (*loc. cit.*) Pl. II, Fig. 19.

5 *Chondrococcus blasticus* Beebe. (*Iowa State Col. Jour. Sci.*, 15, 1941, 310.)

**Etymology:** Greek *blastikos*, budding.

**Fruiting body:** Primary: Spherical to subspherical, usually sessile but occasionally with a short stalk or foot; pale pink to bright salmon pink; 300 to 600 microns in diameter. No outer wall or limiting membrane evident. Develops on sterilized rabbit dung in from 3 to 6 days at room temperature. Secondary: Arising as bud-like growth from the primary fruiting body. Develops into irregularly shaped, finger-, coral- or bud-like protuberance. Seldom branched; occasionally stalked but usually sessile on

primary fruiting body until latter is utilized in formation of several secondary fruiting bodies. Deep pink to salmon pink in color. Variable in size and shape; 50 to 150 by 75 to 225 microns. No outer wall or limiting membrane evident.

**Spores:** Spherical, thick-walled, highly refractile; 1.2 to 1.4 microns in diameter. Held together in the fruiting body by the mass of slime.

**Vegetative cells:** Long, slender, flexible rods, straight or curved to bent, ends rounded to slightly tapered, Gram-negative. 0.5 to 0.6 by 3.0 to 5.0 microns. Usually found in groups of 2 to 12 lying parallel on the surface of the slimy colony, the group moving as a unit. Motile by a crawling or creeping motion, no flagella.

**Vegetative colony:** Thin, colorless, transparent at margin; surface broken by many small ridges or veins. Center smooth, slightly thicker, often showing pale pink color. Fruiting bodies first form at or near center, later distributed irregularly on other parts of colony. Margin composed of active vegetative cells.

**Physiology:** Good growth on mineral salt agar to which has been added such complex carbohydrates as dulcitol, inulin, cellulose, reprecipitated cellulose or starch; starch hydrolyzed, cellulose not destroyed appreciably. Can utilize agar as both C and N sources. Best growth on suspensions of killed bacterial cells in agar. Growth inhibited partially or entirely by arabinose, mannose and maltose.

**Source:** Goat dung and soil, Ames, Iowa.

**Habitat:** Soil. Decomposes organic matter, especially bacterial cells in dung.

**Illustrations:** Beebe (*loc. cit.*) Pl. II, Figs. 5-6, pl. IV, Fig. 18.

6 *Chondrococcus cerebriformis* (Kosler) Jahn. (*Myxococcus cerebriformis* Kosler, Sitzber. d. kais. Akad. Wiss., Wien. Math.-Nat. Klasse, 122

1. Cysts 60 to 170 microns, without definite envelope, in swollen brain-like arrangement

6 *Chondrococcus cerebriformis*.

2. Cysts 30 to 35 microns, numerous, and embedded in a thick slime envelope

1b *Chondrococcus coralloides* var.  
*polycystus*.

## II. Parasitic on fish.

7 *Chondrococcus columnaris*

1 *Chondrococcus coralloides* (Thaxter) Jahn (*Myxococcus coralloides* Thaxter, Bot. Gaz., 17, 1892, 404; *Myxococcus digitatus* Quehl, Cent f Bakt., II Abt., 16, 1906, 18 (*pro parte*); *Myxococcus clavatus* Quehl, *ibid*; *Myxococcus polycystus* Kofler, Sitzberg. d. kais. Wiss., Wien Mat.-Nat. Klasse, 122 Abt., 1913, 865 (*pro parte*); *Myxococcus exiguus* Kofler, *ibid*, 867 (*pro parte*); *Chondrococcus polycystus* Krzemieniewski, Act Soc. Bot. Poloniae, 4, 1926, 46)

Etymology Greek *korallion*, coral, *eidos*, like

Swarm stage (pseudoplasmodium) Rod masses pale pinkish, thin, rods slender, curved 4 to 7 by 0.4 microns. Readily cultivated on lichens and on potato agar

Fruiting bodies: Very variable in shape, usually with rounded coral-like processes, recumbent or upright, sometimes with finger-like outgrowths or rounded constrictions, usually small, about 50 microns in diameter, protuberances 20 to 30 microns wide, light rose to flesh color. Spores 1 to 1.2 microns. Jahn concludes that the species segregated by Quehl and by Kofler are of varietal rank only. Krzemieniewski (1926) regards *Chondrococcus polycystus* (Kofler) Krzemieniewski as a distinct species.

Source and habitat: Thaxter (1892), uncommon in America, on lichens. Very common in Europe. Jahn (1921), relatively common. On dung of rabbit, hare, horses, deer, old bark and old lichens. Goat dung from Lapland and Italy. Kofler (1913), dung of field mice, horses, hares, goats, roe and deer. Krzemieniewski (1927), common in Polish soil.

Illustrations Thaxter (1892, *loc. cit.*) Pl. 24, Figs. 29-33. Quehl (1906, *loc. cit.*) Pl. 1, Figs. 1 and 9. Kofler (1913, *loc. cit.*) Pl. I, Fig. 4, Pl. 2, Fig. 9. Krzemieniewski (1926, *loc. cit.*) Pl. II, Figs. 15-18. Jahn (1921, *loc. cit.*) Fig. Y, p. 87.

1a. *Chondrococcus coralloides* var. *clavatus* varies from *Chondrococcus coralloides* in having fruiting bodies simple or branched rather than constricted or jointed.

1b. *Chondrococcus coralloides* var. *polycystus* varies from *Chondrococcus coralloides* in having its fruiting bodies simple swellings or "cyst heaps" rather than branched, and in being recumbent rather than erect.

2. *Chondrococcus cirrhosus* (Thaxter) Jahn. (*Myxococcus cirrhosus* Thaxter, Bot. Gaz., 25, 1897, 409; Jahn, Beiträge zur botanischen Protistologie I. Die Polyangiden, Geb. Borntraeger, Leipzig, 1921, 200)

Etymology Modern Latin from Greek *cirrhos*, tawny

Swarm stage (pseudoplasmodium): Rods 0.8 by 2 to 5 microns

Fruiting bodies Elongate, upright, thickened below, slender above, extended to a rounded point, 50 to 100 microns long, 20 microns in diameter at base, light red to flesh-colored. Spores about 1 micron.

Source and habitat: Thaxter (*loc. cit.*), once only on grouse dung, Mass.

Illustrations Thaxter (*loc. cit.*) Pl. 31, Figs. 25-27

3 *Chondrococcus megalosporus* Jahn. (Beiträge zur botanischen Protistologie.

**Etymology:** Greek *diskos*, a quoit, discus; Latin *formis*, shape.

**Swarm stage (pseudoplasmodium):** Rods 0.5 to 0.6 by 2 to 3 microns.

**Fruiting bodies:** Cysts disk-shaped, crowded, sessile, attached by a more or less ragged scar-like insertion, or in masses. Cysts yellowish when young, when old dark orange-yellow, about 35 by 10 microns. Cyst wall distinct, thin, becoming very slightly wrinkled. Spores irregularly spherical, embedded in vis-

or envelope. Usually 1 to 3 short stalks or cystophores up to 10 microns high. Within outer wall are numerous cysts containing resting cells (spores). Cysts have regularly rounded form; unpigmented to yellow; 5 to 15 microns in diameter, average 6 microns. Number of cysts in fruiting body increases with age.

**Spores:** Cocci (term used is shortened rods) combined into globular aggregations easily broken up. Size not given.

**Vegetative cells:** 0.4 to 0.5 by 1.5 to 2.0 microns. Cell contents pigmented gray, and of indefinite outline (?).

**Vegetative colony:** Fairly rapid growth on cellulose with silica gel. Colony has a yellowish cast. Reaches diameter of 1.5 to 2.0 cm after 6 days with center yellowish-pink and margin tinged light pink. Surface moist. Fruiting bodies more numerous at center, but distributed over entire area. Fruiting bodies do not noticeably protrude above the surface of the colony.

**Physiology:** Cellulose attacked but not completely destroyed. Lower fibers remain intact, but on treatment with hot soda solution they fall apart.

**Habitat:** Soils.

(1927, *loc. cit.*), rare in Polish soils.

**Illustrations:** Thaxter (*loc. cit.*) Pl. 27, Figs. 19-21. Krzemieniewski *Acta Soc. Bot. Poloniae*, 4, 1926, Pl. II, Figs. 21-22.

2. *Angiococcus cellulorum* Mishustin. (*Microbiology*, Moscow, 7, 1938, 427.)

**Etymology:** Modern Latin *cellulosum*, cellulose.

**Fruiting body:** Regularly rounded (less frequently extended or angular), 20 to 150 microns in diameter; yellow or pink in color, to drabish when old. Encysted cells surrounded by a colorless cyst wall

#### Genus IV. *Sporocytophaga* Stanier.

(*Jour. Bact.*, 40, 1940, 629.)

**Diagnosis:** Spherical or ellipsoidal microcysts formed loosely in masses of slime among the vegetative cells. Fruiting bodies absent.

**Etymology:** Greek *sporos* seed, spore; *kytos* hollow place, cell and *phagein* to eat. The type species is *Sporocytophaga myzococcoides* (Krzemieniewska) Stanier.

#### Key to the species of genus *Sporocytophaga*.

##### I. Microcysts spherical.

##### A. Does not utilize starch.

1. *Sporocytophaga myzococcoides*.

##### B. Utilizes starch.

2. *Sporocytophaga congregata*.

##### II. Microcysts ellipsoidal.

3. *Sporocytophaga ellipsospora*.

Abt., 1913, 866; Jahn, Beiträge zur botanischen Protistologie. I. Die Polyan-giden, Geb. Borntraeger, Leipzig, 1924, 86.)

Etymology. Latin *cerebrum*, brain; *formis*, shape.

Swarm stage (pseudoplasmodium): Rods 4 to 12 microns.

Fruiting bodies: About 1 mm long, clumped masses with swollen upper surface, brain-like, violet rose, often lead-gray. Cysts 100 to 170 microns, without slime envelope. Spores 1.1 to 1.6 microns. Jahn (*loc. cit.*) suggests that this may be *Archangium gephyra*.

Source and habitat: Kofler (*loc. cit.*), on hare dung in the vicinity of Vienna.

Illustrations: Kofler (*loc. cit.*) Pl. 2, Figs 7 and 8.

7. *Chondrococcus columnaris* (Davis) Ordal and Rucker. (*Bacillus columnaris* Davis, Bull. U. S. Bur. Fisheries, 33, 1923, 261, Ordal and Rucker, Proc. Soc. Exper. Biol. and Med., 56, 1944, 18, also see Fish and Rucker, Trans. Amer. Fish. Soc., 73, 1944 in press; *Cytophaga columnaris* Garnjobst, Jour. Bact., 49, 1945, 113.)

Etymology. From Latin *columnaris*, rising in the form of a pillar.

Vegetative cells: Flexible, weakly

refractive, Gram-negative rods, 0.5 to 0.7 by 4 to 8 microns. Creeping motion observed on solid media, and flexing movements in liquids.

Spores (microcysts). 0.7 to 1.2 microns, spherical to ellipsoidal, occurring on both liquid and solid media.

Physiology. Growth best on 0.5 to 0.9 per cent agar with 0.25 to 0.50 per cent Bactotryptone at pH 7.3. Colonies on tryptone agar yellow, flat and irregular. Edge uneven with swarming apparent. Gelatin liquefied rapidly. No indole. No reduction of nitrates. Starch, cellulose and agar not attacked. Sugars not fermented, but glucose oxidized.

Fruiting bodies on agar not deliquescent, and surrounded by a firm membrane. A peculiar type of fruiting body formed in liquid media. Where organisms are in contact with infected tissues or with scales, produce columnar, sometimes branched, fruiting bodies in which typical spores (microcysts) develop in 7 to 10 days.

Source and habitat: First described as cause of bacterial disease of warm water fishes (Davis, *loc. cit.*) and later in fingerlings of the cold water blue black salmon (*Oncorhynchus nerka*). Transmissible to salmonid fishes.

### Genus III. *Angiococcus* Jahn.

(Beiträge zur Protistologie I Die Polyan-giden, Geb. Borntraeger, Leipzig, 1924, 89.) A segregate from *Myxococcus* Thaxter.

Diagnosis. Fruiting body consisting of numerous round (disk shaped) cysts, cyst wall thin, spores within.

Etymology. Greek *angion*, vessel and *kokkos*, coccus (ball).

The type species is *Angiococcus disciformis* (Thaxter) Jahn.

#### Key to the species of genus *Angiococcus*.

- A. Cysts yellow to dark orange yellow, disk shaped, 35 microns in diameter.
  - 1. *Angiococcus disciformis*
- B. Cysts colorless to yellow, round, up to 15 microns in diameter.
  - 2. *Angiococcus cellulorum*

1. *Angiococcus disciformis* (Thaxter) Jahn. (*Myxococcus disciformis* Thaxter, Bot. Gaz., 37, 1904, 412, Jahn, Beiträge zur botanischen Protistologie. I. Die Polyan-giden, Geb. Borntraeger, Leipzig, 1924, 89.)

(Cent. f. Bakt., I Abt., Orig., 96, 1925, 426.) From sea water.

*Spirochaeta minima* Dobell. (Dobell, Arch. f. Protistenk., 26, 1912, 117; not *Spirochaeta minima* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 187 (*Treponema minimum* Beaurepaire-Aragão and Vianna, Mem. Inst. Oswaldo Cruz, 5, 1913, 211).) One of the smallest known *Spirochaeta*, 0.5 by 2.0 to 2.5 microns. From water of the river Granta at Cambridge. Similar to *Spirochaeta fulgurans*.

*Spirochaeta virax* (Dobell) Zuelzer. (*Treponema virax* Dobell, Arch. f. Protistenk., 26, 1912, 117, Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., 3,

1931, 1669.) From fresh water of the river Granta at Cambridge

*Spirochaete kochii* Trevisan. (Spirochaete des Wollsteiner See, Koch, in Cohn, Beitr. z. Biol. d. Pflanzen, 2, Heft 3, 1877, 420; Trevisan, Batter. Ital., 1879, 26; *Spirillum kochii* Trevisan, I generi e le specie delle Batteriacee, 1889, 24.) From water.

*Spirochaete schroeteri* Cohn. (Jahresber. d. Schles. Gesellsch. f. 1883, 198; quoted from Schroeter, in Cohn, Kryptog. Flora v. Schlesien, 3, 1, 1889, 168; *Spirillum schroeteri* Cohn, quoted from DeToni and Trevisan, in Saccardo, Sylloge Fungorum, 8, 1893, 1007.) Similar to *Spirochaete cohnii*. From cellar walls.

## Genus II. *Saprospira* Gross.

(Mittheil. Zool. Stat. zu Neapel, 20, 1911, 190.)

Spiral protoplasm without evident axial filament. Spirals rather shallow. Transverse markings or septa (?) seen in unstained and stained specimens. Periplast membrane distinct. Motility active and rotating. Free-living in marine ooze.

The type species is *Saprospira grandis* Gross.

1 *Saprospira grandis* Gross. (Mittheil. Zool. Station zu Neapel, 20, 1911, 190.) From Latin, great.

Cylindrical, 12 by 80 microns in length, with obtuse ends

Spiral amplitude is 24 microns.

Waves large, inconstant, shallow, irregular, 3 to 5 in number, sometimes almost straight.

Axial filament absent.

Cross-striations present.

Membrane distinct

Division transverse

Flexible, elastic

Crista absent.

Axial filament absent

Source Found in intestinal tract of the oyster.

Habitat. Free-living in foraminiferous sand.

(Jour. Bact., 12, 1926, 146.) From Latin, pitted.

Large spirals: 1.0 by 86 microns with pointed ends.

The spiral amplitude is 4 to 8 microns.

The average number of turns is 3.

Axial filament absent.

Cross-striations present.

Membrane distinct.

Division transverse.

Source Found in oysters.

3 *Saprospira lepta* Dimitroff. (Jour. Bact., 12, 1926, 144.) From Latin, small.

Large spirals: 0.5 by 70.0 microns, with pointed ends.

The spiral amplitude ranges from 5 to 13 microns.

The spiral width varies from 1.6 to 4.8 microns.

The average number of turns is 6.

Axial filament absent.

Cross-striations present.

2. *Saprospira puncta* Dimitroff.

1. *Sporocytophaga myxococcoides* (Krzemieniewska Stanier. (*Spirochaeta cytophaga* Hutchinson and Clayton, Jour. Agr. Sci., 9, 1919, 150; *Cytophaga myxococcoides* Krzemieniewska, Arch Mikrobiol., 4, 1933, 400; *Cytophaga globulosa* Stapp and Bortels, Cent f Bakt., II Abt., 90, 1934, 47, *Cytophaga hutchinsonii* Imšenecki and Solntzeva, Bull. Acad. Sci. U.S.S.R., Ser. Biol., No 6, 1936, 1129; not *Cytophaga hutchinsonii* Winogradsky, Ann. Inst. Pasteur, 43, 1929, 578; Stanier, Jour. Bact., 40, 1940, 630)

Etymology. Modern Latin from generic name *Myxococcus*, and *eidos*, like

Vegetative morphology: Flexible, singly occurring rods, 0.3 to 0.4 micron wide at the center, tapering to both ends. Length 3 to 8 microns according to Krzemieniewska (*loc cit*), 2.5 to 5 microns according to Jensen (Proc. Linn Soc N So Wales, 65, 1940, 547). May be straight, bent, U-shaped or S-shaped. Show creeping motility (Stapp and Bortels, *loc cit*). Stain poorly with ordinary aniline dyes; with Giemsa's stain, the young cells are colored uniformly except for the tips. As the rods shorten and swell to form microcysts, the chromatin becomes concentrated and moves toward the center of the cell, generally in the form of two parallel bands (Krzemieniewska, Acta Soc Bot Pol., 7, 1930, 514).

Microcysts: Spherical, 1.3 to 1.6 microns in diameter, covered with a sheath of mucus. According to Krzemieniewska (1930, *loc cit*), germination is by emergence of the shortened rod from the sheath, followed by elongation; according to Stapp and Bortels (*loc cit*) and Imšenecki and Solntzeva (*loc cit*), by a simple elongation of the entire microcyst.

Growth is strictly confined to cellulose. On mineral salts-silica gel plates covered with filter paper, yellow, glistening, slightly mucilaginous patches are pro-

duced after a few days. The color gradually assumes a light brownish tinge on aging. The filter paper in these regions is eventually completely dissolved and the patches become translucent.

Ammonia, nitrate, asparagin, aspartic acid and peptone can serve as sources of nitrogen (Jensen, *loc. cit.*).

Strictly aerobic.

Optimum temperature 28 to 30°C.

Source: Isolated from soil.

Habitat: Soil. Decomposes cellulose.

2 *Sporocytophaga congregata* Fuller and Norman. (Jour. Bact., 45, 1943, 567.)

Etymology: Latin *congrēgo*, to assemble.

Vegetative cells are long, flexuous rods with pointed ends, 0.5 to 0.7 by 5.5 to 8.0 microns. Creeping motility on solid surfaces.

Spores (microcysts): Spherical, 0.7 to 1.1 microns in diameter. Usually occur in localized regions within the colony.

Growth on starch agar is smoky, later turning yellow. Colonies are irregularly round, slightly concave. Edge is smooth.

cells gather into groups and in these regions a large number of spherical spores are found.

Growth on cellulose dextrin agar is pale; colonies are small and concave. Hollowing of the agar is limited to the area of colony growth.

Glucose, galactose, lactose, maltose, sucrose, arabinose, calcium gluconate, starch, cellulose dextrin, pectin, and hemicellulose are utilized. Filter paper is not attacked.

Ammonium, nitrate, and peptone are suitable nitrogen sources.

Indole not formed.

Nitrates not produced from nitrates.

kaiserl. Gesundheitsamte, 30, 1909, 379; Bergey et al., Manual, 1st ed., 1923, 423.) From Latin, of a mussel.

Spirals: 0.5 to 3.0 by 10 to 60 microns, round in section with blunt ends, the one being slightly more pointed than the other.

They have a ridge or comb running along one side but no terminal filaments.

Cross-striations distinct.

The chromatin granules are grouped in fours.

An undulating membrane can be demonstrated.

Source: Found in the intestinal canal of the scallop (*Pecten jacobaeus*).

Habitat: From the crystalline style of molluscs.

**Appendix:** Additional species which appear to belong in this genus are:

*Cristispira acuminata* (Schellack) Ford. (*Spirochaeta acuminata* Schellack, Arb. kais. Gesundheitsamte, 30, 1909, 379, not *Spirochaeta acuminata* Castellani, Brit. Med. Jour., 2, 1903, 1330; Ford, Textb. of Bact., 1927, 939.) From the crystalline style of a mollusc, *Tapes lactea*.

*Cristispira cardui-papillosum* (Schellack) Ford. (*Spirochaeta cardui-papillosum* Schellack, Arb. kais. Gesundheitsamte, 30, 1909, 379, Ford, Textb. of Bact., 1927, 939.) From the crystalline style of a mollusc, *Cardium papillosum*.

*Cristispira chamae* (Schellack) Noguchi. (*Spirochaeta chamae* Schellack, Arb. kais. Gesundheitsamte, 30, 1909, 379; Noguchi, Jour. Exp. Med., 27, 1918, 583.) From the crystalline styles of molluscs, *Chama* spp.

*Cristispira gastrochaenae* (Schellack) Ford. (*Spirochaeta gastrochaenae* Schellack, Arb. kais. Gesundheitsamte, 30, 1909, 379; Ford, Textb. of Bact., 1927, 940.) From a shellfish, *Gastrochaena dubia*. Constant length 29 microns.

*Cristispira helgolandica* Collier. (Cent. f. Bakt., I Abt. Orig., 86, 1921, 132.) Found three times in the body

fluid of an echinoderm, *Asterias rubens*, in the North sea. Average length 68 microns. Named for the place where the investigation was made (Helgoland).

*Cristispira interrogationis* Gross. (Mittheil. Zool. Station zu Neapel, 20, 1910, 41.) From the intestinal canal of the scallop, *Pecten jacobaeus*.

*Cristispira lima* (Schellack) Ford. (*Spirochaeta lima* Schellack, Arb. kais. Gesundheitsamte, 30, 1909, 379; Ford, Textb. of Bact., 1927, 939.) From the crystalline styles of molluscs, *Lima* spp. Similar to *Cristispira balbianii*.

*Cristispira mactrae* (Prowazek) Ford. (*Spirochaeta mactrae* Prowazek, Arch. f. Schiff- u. Tropenhyg., 14, 1910, 297; Ford, Textb. of Bact., 1927, 940.) From the digestive tract of a shellfish, *Mactra sulcataria*.

*Cristispira mina* Dimitroff. (Jour. Bact., 12, 1926, 159.) Found in oysters.

*Cristispira modiolae* (Schellack) Noguchi. (*Spirochaeta modiolae* Schellack, Arb. kais. Gesundheitsamte, 30, 1909, 379; Noguchi, Jour. Exp. Med., 27, 1918, 583.) Found in mussels and oysters.

*Cristispira ostreae* (Schellack) Noguchi. (*Spirochaeta ostreae* Schellack, Arb. kais. Gesundheitsamte, 30, 1909, 379; Noguchi, Jour. Exp. Med., 27, 1918, 583.) From the crystalline style of the oyster, *Ostrea edulis*. Identical with *Cristispira anodontae* Gross.

*Cristispira pachelabrae* de Mello. (Compt. rend. Soc. Biol., Paris, 84, 1921, 241.) From the digestive tract of a shellfish, *Pachelabra moestra*.

*Cristispira parvula* Dobell. (Arch. f. Protistenk., 26, 1912, 117.) From the crystalline style of a mollusc, *Venus* (*Meretrix*) castra, in Ceylon. The smallest *Cristispira* known—0.4 to 0.5 by 20 to 45 microns.

*Cristispira pectinis* Gross. (Mittheil. Zool. Sta. zu Neapel, 20, 1910, 41.) From the digestive tract of a scallop, *Pecten jacobaeus*. Identical with *Cristispira balbianii* Gross.

*Cristispira polydora* Mesnil and Caul-

Membrane distinct.

Division transverse.

Source: Found in oysters in Baltimore, Maryland.

*Saprospira flexuosa* Dobell. (Arch. f. Protistenk., 26, 1912, 117.) Isolated once from water of the river Granta at Cambridge.

*Saprospira nana* Gross. (Mittheil. Zool. Sta. zu Neapel, 26, 1911, 188.) From foraminiferous sand.

Appendix: The following species have been placed in this genus.

### Genus III. *Cristispira* Gross.

(Mittheil. Zool. Stat. zu Neapel, 20, 1910, 41.)

Flexuous cell bodies in coarse spirals, 23 to 120 microns in length. Characterized by a crista or thin membrane of varying prominence on one side of the body extending the entire length of the organism. Cross-striations. Actively motile. Found in the intestinal tract of molluscs.

The type species is *Cristispira balbianii* (Certes) Gross.

1. *Cristispira balbianii* (Certes) Gross. (*Trypanosoma balbianii* Certes, Bull. Soc. Zool. de France, 7, 1882, 317; *Spirochaeta balbianii* Swellengrebel, Ann. Inst. Past., 21, 1907, 562; *Spirochaeta balbianii* Borrel and Cernovodeanu, Compt. rend. Soc. Biol., Paris, 62, 1907, 1102; Gross, Cent. f. Bakt., I Abt., Orig., 65, 1912, 90)

Cylindrical: 10 to 30 by 10 to 120 microns, with obtuse ends

Spiral amplitude is 8 microns. Spiral depth is 16 microns. Waves 2 to 5, sometimes more, large, irregular, shallow.

Axial filament absent

Cross striations present

Membrane distinct

Flexible, elastic.

Crista present, a ridge-like membrane making one to two complete turns

Terminal spiral filament absent

Highly motile end portion absent

Stains. Cell membrane behaves like chitin or cutin substance. Stains violet by Gram's solution, and light gray by iron hematoxylin.

Trypsin digestion: Membrane resistant, crista and striations disappear.

Bile salt (10 per cent). Crista quickly dissolves

Saponin (10 per cent). Crista becomes fibrillar, then indistinct.

Source: From the crystalline style of oysters.

Habitat: Parasitic in alimentary tract of shell-fish.

2 *Cristispira anodontae* (Keysseltz) Gross (*Spirochaeta anodontae* Keysseltz, Arb. a. d. kaiserl. Gesundheitsamte, 23, 1906, 566; Gross, Cent. f. Bakt., I Abt., Orig., 65, 1912, 900) From M. l., muscles

0.8 to 1.2 by 41 to 55 microns with sharply pointed ends, flattened and possessing an undulating membrane. The periplast is fibrillar in appearance and there is a dark granule at each end of the undulating membrane. The chromatin material is distributed in the form of globules or elongated bands.

Large spirals. The average width of the spiral is 2 microns. The average wave length is 8 microns.

The number of complete turns ranges from 5 to 11

Habitat. Found in the crystalline style of fresh water muscles, *Anodonta cygnea* and *A. multabilis*, also in intestinal tract of oysters

3 *Cristispira pinnae* (Gonder) Berkey et al. (*Spirochaeta pinnae* Gonder, Cent. f. Bakt., I Abt., Orig., 47, 1910, 491; *Spirochaeta pinnae* Schellack, Arb. a. d.

## FAMILY II. TREPONEMATACEAE SCHAUDINN.

(Deutsche med. Wochenschr., 31, 1905, 1728.)

Coarse or slender spirals, 4 to 16 microns in length; longer forms due to incomplete or delayed division. Protoplasm with no obvious structural features. Some may show terminal filaments. Spirals regular or irregular, flexible or comparatively rigid. Some visible only with dark field illumination. Parasitic on vertebrates with few exceptions. Some pathogenic. Many can be cultivated.

## Key to the genera of family Treponemataceae.

I. Stains easily with ordinary aniline dyes.

Genus I. *Borrelia*, p. 1058.

II. Stain with difficulty except with Giemsa's stain and silver impregnation.

A. Strict anaerobes.

Genus II. *Treponema*, p. 1071.

B. Aerobes.

Genus III. *Leptospira*, p. 1076.Genus I. *Borrelia*\* Swellengrebel.

(Swellengrebel, Ann. Inst. Past., 21, 1907, 582; *Spiroschaudinna* Sambon, in Manson, Tropical Diseases, August, 1907, 833, *Cacospira* Enderlein, Sitzber. Ges. Naturf. Freunde, Berlin, 1917, 309; *Entomospira* Enderlein, *ibid.*; *Spironema* Bergey et al., Manual, 1st ed., 1923, 424; not *Spironema* Vuillemin, Compt. rend. Acad. Sci. Paris, 140, 1905, 1567; *Spirochaeta* Gieszczykiewicz, Bull. Acad. Polonaise d. Sci. et Lettres, Cl. Sci. Math. et Nat., Sér. B, 1939, 24.)

Length 8 to 16 microns. Coarse, shallow, irregular, with a few obtuse angled spirals. Generally taper terminally into fine filaments. Stain easily with ordinary aniline dyes. Refractive index approximately the same as that of true bacteria. Parasitic upon many forms of animal life. Some are pathogenic for man, other mammals and birds. Generally hematophytes are found on mucous membranes. Some are transmitted by the bites of arthropods.

The type species is *Borrelia anserina* (Sakharoff) Bergey et al.

1. *Borrelia anserina* (Sakharoff) Bergey et al. (*Spirochaeta anserina* Sakharoff, Ann. Inst. Past., 5, 1891, 564; *Spirillum anserum* (sic) Sternberg, Man. of Bact., 1893, 499; *Spirillum anserinum* Macé, Traité Pratique de Bact., 4th ed., 1901, 1060, *Spirochaete anserina* Macé, *ibid.*; *Spiroschaudinna anserina* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 403; *Spironema anserina* Noguchi, Jour. Exp. Med., 27, 1918, 584; Bergey et al., Manual, 2nd ed., 1925, 435, *Treponema anserina* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 456.) From Latin, pertaining to geese

Synonyms: *Spirochaeta marchouzi* Nuttall, Epidemiol. Soc., London, 24, 1904, 12 (Spirille de la poule, Marchoux and Salimbeni, Ann. Inst. Past., 17, 1903, 569, *Spirochaeta gallinarum* Stephens and Christopher, Practical Study of Malaria and Other Blood Parasites, Liverpool, 1905; *Borrelia gallinarum* Swellengrebel, Ann. Inst. Past., 21, 1907, 623; *Spirochaete gallinarum* Lehmann and Neumann, Bakt. Diag., 4 Aufl., 2, 1907, 623; *Spironema gallinarum* Gross, Cent. f. Bakt., I Abt., Orig., 65, 1912, 92; *Spiroschaudinna marchouzi* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 403; *Spironema marchouzi* Ford,

\*Further revision of the genus by Prof. E. G. D. Murray, McGill Univ., Montreal, P. Q., Canada, April, 1947. Reviewed by Dr. Gordon E. Davis, Rocky Mountain Laboratory, U.S.P.H.S., Hamilton, Montana.

lery. (Compt. rend. Soc. Biol., Paris, 79, 1916, 1118; *Cristispiraella polydora* Hollande, Compt. rend. Acad. Sci. Paris, 172, 1921, 1696). From a marine annelid, *Polydora flava*.

*Cristispira pusilla* (Schellack) Ford. (*Spirochaeta pusilla* Schellack, Arb. kais. Gesundheitsamte, 30, 1909, 379; Ford, Textb. of Bact., 1927, 940) From the digestive tract of a mussel, *Anodonta mutabilis*.

*Cristispira saxicavae* (Schellack) Ford (*Spirochaeta saxicavae* Schellack, Arb. kais. Gesundheitsamte, 30, 1909, 379, Ford, Textb. of Bact., 1927, 940) From the crystalline style of a mollusc, *Saxicava arctica*.

*Cristispira spiculifera* (Schellack) Dimitroff. (*Spirochaeta spiculifera* Schellack, Arb. kais. Gesundheitsamte, 30, 1909, 379, Dimitroff, Jour. Bact., 12, 1926, 157.) Found in mussels.

*Cristispira tapetos* (Schellack) Gross (*Spirochaeta tapetos* Schellack, Arb.

kais. Gesundheitsamte, 30, 1909, 379; Gross, Cent. f. Bakt., I Abt., Orig., 65, 1912, 84.) From the crystalline style of a mollusc, *Tapes decussata*.

*Cristispira tenua* Dimitroff. (Jour. Bact., 12, 1926, 160.) Found in oysters.

*Cristispira teneris* Dobell. (Quart. Jour. Microsc. Sci., London, 54, 1910-1911, 507 and *ibid*, 56, 1911, Part 3) From a clam, *Venus (Meretrix) castra*, in Ceylon. Identical with *Cristispira balbiani* Gross.

*Cristispiraella caviae* Hollande. (Compt. rend. Acad. Sci., Paris, 172, 1921, 1693) From the intestine of a guinea pig. Probably a protozoan. Evidently the same as *Heliconema* (see appendix to *Borrelia*). Both *Cristispiraella polydora* and *Cristispiraella caviae* have characteristics at variance with accepted ideas of spirochaetes.

*Spirochaeta solentis* Fantham. (Ann. Trop. Med. and Parasitol., 5, 1911, 479.) A parasite of a mollusc, *Solen ensis*.

## MANUAL OF DETERMINATIVE BACTERIOLOGY

- bb. Non-motile.
  - c. Grows readily at 37°C.
    - 16. *Pseudomonas smaragdina*.
  - cc. Grows poorly or not at all at 37°C.
    - 17. *Pseudomonas chlorina*.
- aa. Gelatin not liquefied.
  - b. Polar flagellate.
    - c. Grow readily at 37°C. Usually bluish-green.
      - 18. *Pseudomonas oleovorans*.
      - 19. *Pseudomonas incognita*.
      - 20. *Pseudomonas convexa*.
      - 21. *Pseudomonas maldenbergis*.
    - cc. Grow poorly or not at all at 37°C.
      - d. Milk not coagulated.
        - 22. *Pseudomonas putida*.
        - 23. *Pseudomonas scissa*.
        - 24. *Pseudomonas ovalis*.
        - 25. *Pseudomonas striata*.
        - 26. *Pseudomonas denitrificans*.
      - dd. Milk coagulated.
        - 27. *Pseudomonas solaniolens*.
    - bb. Non-motile.
      - c. Grows poorly.
        - d. Milk not coagulated.
          - 28. *Pseudomonas eisenbergii*.
- 2. Green fluorescent pigment.
  - a. Gelatin liquefied.
    - b. Polar flagellate.
      - c. Grow poorly or not at all at 37°C. No visible gas from sugar fermentation.
        - d. I. rapid reduction litmus. Putrid odor.
          - 29. *Pseudomonas putrefaciens*.
        - dd. Slow reduction litmus. Alkaline.
          - 30. *Pseudomonas mephitica*.
          - 31. *Pseudomonas geniculata*.
        - ddd. Acid coagulated.
          - 32. *Pseudomonas fragi*.
      - cc. Acid and visible gas from glucose. Optimum temperature I. variable.
        - d. Litmus milk reduced and alkaline.
          - 33. *Pseudomonas nebulosa*.
        - dd. Litmus milk acid coagulated.
          - 34. *Pseudomonas coadunata*.
          - 35. *Pseudomonas multistriata*.
          - 36. *Pseudomonas punctata*.
          - 37. *Pseudomonas hydrophila*.
          - 38. *Pseudomonas ichthyosmia*.

Textb. of Bact., 1927, 955; *Spirochaeta gallinae* Ford, *idem*; *Treponema gallinarum* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461; *Treponema marchouxi* Gay et al., Agents of Disease and Host Resistance, 1935, 1077). The cause of septicæmia in chickens.

*Spirochaeta granulosa penetrans* Balfour, Jour. Trop. Med and Hyg., 10, 1907, 153 (*Spiroschaudinna granulosa* Balfour, Jour. Trop. Veter., Calcutta, 5, 1910, 309; *Spirochaeta granulosa* Ford, Textb. of Bact., 1927, 957) From spirochetosis of fowls in Sudan.

*Spirochaeta nicolleti* Brumpt, Bull. Soc. Path. Exot., 2, 1909, 285 and/or Précis de Parasitol., Paris, 1st ed., 1910 (Galli-Valerio, Cent. f. Bakt., I Abt., Orig., 50, 1909, 189 and 61, 1912, 529; *Spirochaeta nicolleti* Ford, Textb. of Bact., 1927, 958; *Treponema nicolleti* Gay et al., Agents of Disease and Host Resistance, 1935, 1077) From spirochetosis of geese in Tunisia.

*Spirochaeta neweuzi* Brumpt, Bull. Soc. Path. Exot., 2, 1909, 285 (*Spiroschaudinna neweuzi* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 404; *Spirochaeta neweuzi* Ford, Textb. of Bact., 1927, 958, *Treponema neweuzi* Gay et al., Agents of Disease and Host Resistance, 1935, 1077). The cause of fowl spirochetosis in Senegal.

*Spirochaeta gallinarum* var. *hereditaria* Neumann and Mayer, in Lehmann, Med. Atlanten, 11, 1914, 276. A North African strain of fowl spirochetosis.

*Borrelia pullorum* Redowitz, Amer. Jour. Med. Technol., 2, 1936, 91. From diseased chickens.

*Spirochaeta anatoli* Parrot, Bull. Soc. Path. Exot., 13, 1920, 617. Pathogenic for domestic ducks in Algeria.

Morphology. 0.25 to 0.3 by 8 to 20 microns, averaging about 1 spiral per micron.

Actively motile, with lashing movements.

Stains readily with aniline dyes and Giemsa's stain.

Cultivation: Can be cultivated in Noguchi's ascitic fluid-rabbit kidney medium.

Immunology: Antigenically distinct from species found in mammals.

Arthropod vectors: Transmitted by the bites of ticks (*Argas persicus*, *A. miniatus*, *A. reflexus* and *Ornithodoros moubata*).

Pathogenic for birds but not for mammals.

Source: From blood of infected geese, ducks, fowls and vector ticks.

Habitat: The cause of spirochetosis of fowls.

2 *Borrelia recurrentis* (Lebert) Bergey et al. (Obermeier, Berlin klin. Wochenschr., 1873, 152; *Protomyxetum recurrentis* Lebert, Ziemssen's Handbuch, 2, 1874, 267; *Spirochaete obermeieri* Cohn, Beitr. z. Biol. d. Pflanzen, 1, Heft 3, 1875, 196; *Spirillum obermeieri* Zopf, Die Spaltpilze, 3 Aufl., 1885, 71; *Spirochaeta obermeieri* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 35; *Spirochaete recurrentis* Lehmann and Neumann, Bakt. Diag., 4 Aufl., 2, 1907, 621; *Spirochaeta recurrentis* Castellani and Chalmers, Man. Trop. Med., 1st ed., 1910, 305; *Spirochaeta recurrentis* Gross, Cent. f. Bakt., I Abt., Orig., 65, 1912, 85; *Spiroschaudinna recurrentis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 398, *Spirochaeta obermeieri* Park and Williams, Pathogenic Microorganisms, 6th ed., 1917, 513, *Cacospira recurrentis* Enderlein, Sitzungsber. d. Gesellsch. natürl. Freunde, 1917, 313; *Treponema recurrentis* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 508, *Treponema obermeieri* Brumpt, *ibid.*; *Cacospira obermeieri* Enderlein, Bakterien-Cylogenie, 1925, 254, Bergey et al., Manual, 2nd ed., 1925, 433, *Spirillum recurrentis* Ford, Textb. of Bact., 1927, 918, *Spiroschaudinna obermeieri* Ford, *ibid.*) From Latin, recurring.

Cylindrical or slightly flattened, 0.35 to 0.5 by 8 to 16 microns, with pointed ends.

Spiral amplitude 1.5 microns.

Spirals large, wavy, inconstant, about 5 in number.

Terminal finely spiral filaments present.

Highly motile end portion absent.

Motility: By active cork-screw motion without polarity. Lashing movements common in drawn blood.

Stains with common aniline dyes. Gram-negative. Violet with Giemsa's stain.

Bile salts (10 per cent): Disintegration complete.

Saponin (10 per cent): Immobilized in 30 minutes, then broken up in a few hours. In some a skeletal structure remains.

Cultivation: Can be cultured in ascitic or hydrocoel fluid to which a piece of sterile rabbit kidney is added. Optimum reaction pH 7.2 to 7.4.

Immunology: Serum does not agglutinate *Borrelia duttoni*.

Accidental and experimental transmission by conjunctival sac and skin abrasions.

Disease in experimental animals (small rodents after monkey passage) mild.

Arthropod vector: Louse (*Pediculus humanus*) which exhibits normal transmission from the 16th to the 28th day. Found in the bed-bug (*Cimex lectularius*) and ticks, but not transmitted by them. No evidence of hereditary transmission in the louse.

Habitat: The cause of European relapsing fever. Transmissible to man, monkeys, mice and rats.

3. *Borrelia duttoni* (Novy and Knapp) Bergey et al. (Dutton and Todd, British Med. Jour., 2, 1905, 1259; *Spirillum duttoni* Novy and Knapp, Jour. Infect. Dis., 8, March 18, 1906, 296; *Spirochaeta duttoni* Breinl, Lancet, 1, June 16, 1906, 1690; *Spirochaete duttoni* Lehmann and Neumann, Bakt. Diag., 4 Aufl., 2, 1907, 623; *Spironema duttoni* Gross, Cent. f. Bakt., I Abt., Orig., 65, 1912, 94; *Spirochaeta Micro-*

*spironema duttoni* Duboseq and Lebaill, Compt. rend. Acad. Sci., 154, 1912, 662; *Spiroschaudinna duttoni* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 399; *Treponema duttoni* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 497; *Cacospira duttoni* Enderslein, Bakterien-Cyclogenie, 1925, 254; Bergey et al., Manual, 2nd ed., 1925, 431.) Named for Dutton, who discovered this organism.

Morphology: Similar to *Borrelia recurrentis*.

Cultivation: Growth occurs under anaerobic conditions in serum water, hydrocoel or ascitic fluid to which a piece of sterile rabbit kidney is added.

Immunology: This organism is antigenically distinct from other causes of relapsing fever.

Pathogenic for mice and rats. Disease in small rodents and many other experimental animals very severe.

Arthropod vector: This species is transmitted to man through the bite of the tick (*Ornithodoros moubata*) by fecal contamination of the bite. In the tick the organism goes through some granulation or fragmentation phenomenon, the nature of which is not understood. Hereditary transmission to at least the third generation of the tick. Not transmitted by the louse.

Habitat: The cause of Central and South African relapsing fever.

4. *Borrelia kochii* (Novy) Bergey et al. (*Spirochaeta kochi* Novy, Proc. Path. Soc. Philadel., N. S. 10, 1907, 1; *Spirochaeta rossi* Nuttall, Jour. Roy. Inst. Pub. Health, London, 16, 1908, 385; *Spiroschaudinna rossi* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 400; *Spironema kochii* Noguchi, Jour. Exp. Med., 27, 1918, 584; *Treponema kochi* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 497; *Treponema rossi* Brumpt, *ibid.*; Bergey et al., Manual, 2nd ed., 1925, 434; *Borrelia rossi* Steinhilber, Insect Microbiology, 1946, 452.)

Named for Koch, who first observed spirochetes in East African relapsing fever.

Morphology. Similar to that of *Borrelia recurrentis*.

Cultivation Same as for *Borrelia recurrentis*.

Immunology: Antigenically distinct from both *Borrelia recurrentis* and *B. duttoni*.

Pathogenic for mice and rats

Arthropod vector No record.

Habitat: The cause of African relapsing fever.

5. *Borrelia novyi* (Schellack) Bergey et al. (*Spirochaeta* from relapsing fever, Norris, Pappenheimer and Flournoy, Jour Inf. Dis., 3, 1906, 266, *Spirochaeta novyi* Schellack, Arb. kaiserl. Gesundheitsamte, 27, 1907, 199 and 364, *Spirochaeta novyi* Gross, Archiv f. Protistenk., 24, 1912, 115; *Spiroschaudinna novyi* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 400; *Treponema novyi* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 508, *Cacospira novyi* Enderlein, Bakterien-Cyclogenie, 1925, 254; Bergey et al., Manual, 2nd ed., 1925, 431) Named for Novy, the American bacteriologist

Morphology Similar to that of *Borrelia recurrentis*.

Cultivation Same as for *Borrelia recurrentis*

Immunology. Antigenically distinct from other relapsing fever organisms

Pathogenic for monkeys, white rats and white mice.

Arthropod vector. Unknown

Habitat: Recovered from a patient in Bellevue Hospital, New York. Origin of infection unknown

6. *Borrelia berbera* (Sergeant and Foley) Bergey et al. (*Spirochaeta berbera* Sergeant and Foley, Ann Inst. Past., 24, 1910, 337, *Spiroschaudinna berbera* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 402; *Spironema berbera*

Noguchi, Jour. Exp. Med., 27, 1918, 584, *Spirochaeta berbera* Kolle and Hetsch, Exper. Bakt. u. Infekt., 6 Aufl., 1, 1922, 811; *Treponema berberum* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 496, Bergey et al., Manual, 2nd ed., 1925, 435.) Named for the Berbers, a tribe of Northern Africa

Morphology: More tenuous than other relapsing fever organisms, 0.2 to 0.3 by 12 to 24 microns.

Cultivation: No record of its cultivation.

Immunology: Antigenically distinct from *Borrelia recurrentis*.

Arthropod vector: Possibly carried by the louse (*Pediculus testimentis*).

Source: Found in cases of relapsing fever in Algiers, Tunis and Tripoli.

Habitat: Cause of relapsing fever in North Africa. Is virulent for monkeys. Produces non-fatal infections in rats and mice

7. *Borrelia carteri* (Mackie) Bergey et al. (*Spirochaeta carteri* Mackie, Ann. Trop. Med. and Parasitol., 1, 1907, 157 and Indian Med. Gazette, 44, 1908, 370; *Spirillum carteri* Mackie, Lancet, 2, 1907, 832, according to Ford, Textb. of Bact., 1927, 950; *Spiroschaudinna carteri* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 401; *Spironema carteri* Noguchi, Jour. Exp. Med., 27, 1918, 584; *Treponema carteri* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 497, Bergey et al., Manual, 2nd ed., 1925, 435) Named for Carter, who in 1879 described this organism in the blood of patients with Indian relapsing fever.

Morphology: Similar to *Borrelia berbera*.

Cultivation Not recorded.

Immunology: Probably a distinct species. A succession of distinct serological types occurs with the relapses in a single infection (Cunningham et al., Far Eastern Association of Tropical Medicine, Tokyo, 1925; Indian Journal of Medical

Research, 22, 1934-1935, 105 and 595; *ibid.*, 24, 1937, 571 and 581).

Arthropod vector: Carried by either *Pediculus vestimenti* or *Cimex rotundatus* or by both.

Habitat: The cause of Indian relapsing fever. Transmissible to monkeys, rabbits, rats and mice

8. *Borrelia theileri* (Laveran) Bergey et al. (*Spirochaeta theileri* Laveran, Compt. rend. Acad. Sci., Paris, 186, 1903, 939; *Spiroschaudinia theileri* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 401, *Spironema theileri* Noguchi, Jour. Exp. Med., 27, 1918, 584; Bergey et al., Manual, 2nd ed., 1925, 435; *Spirillum theileri* and *Spirochaeta theileri* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928; *Treponema theileri* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461) Named for Theiler, who discovered this organism in 1902 in Transvaal, South Africa

Morphology. 0.25 to 0.3 micron by 20 to 30 microns with pointed ends.

Cultivation. No record

Immunology. Is distinct from the species infecting man.

Arthropod vector. Transmitted by the tick (*Rhipicephalus decoloratus*)

Source. Blood of cattle.

Habitat. Blood of cattle and other mammals in South Africa

9. *Borrelia glossinae* (Novy and Knapp) Bergey et al. (*Spirillum glossinae* Novy and Knapp, Jour. Inf. Dis., 3, 1906, 385; *Spirochaeta glossinae* Castellani and Chalmers, Man. Trop. Med., 1st ed., 1910, 310, *Spiroschaudinia glossinae* Castellani and Chalmers, *ibid.*, 3rd ed., 1919, 454; *Spironema glossinae* Bergey et al., Manual, 1st ed., 1923, 425; Bergey et al., Manual, 2nd ed., 1925, 435, *Entomospira glossinae* Enderlein, Bakterien-Cyclogenie, 1925, 254; *Treponema glossinae* Ford, Textb. of Bact., 1927,

938.) Named for the genus of insects, *Glossina*.

Morphology: 0.2 by 8.0 microns, occurring singly, sometimes in pairs. Generally 4 spirals. Shorter, narrower and has more turns than has *Borrelia recurrentis*

Habitat: Found in the stomach contents of the tse-tse fly (*Glossina palpalis*).

10. *Borrelia buccalis* (Steinberg) Brumpt. (*Spirochaeta buccalis* Steinberg, 1862, according to Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., 41, 1906, 819; *Spirochaeta cohnii* Winter, Die Pilze, 1879, 61; (?) *Microspira buccalis* Lewis, The Lancet, 1884, quoted from Schroeter, in Cohn, Kryptog. Flora v. Schlesien, 3, 1, 1889, 169; *Spirochaeta buccalis*, quoted from Schroeter, *ibid.*, 168; *Spirillum cohnii* Trevisan, I generi e le specie delle Batteriacee, 1889, 24; *Spirillum buccale* Macé, Traité Pratique de Bact., 4th ed., 1901, 1062; *Spirochaeta inaequalis* Gerber, Cent. f. Bakt., I Abt., Orig., 56, 1910, 508; *Spirochaeta undulata* Gerber, *idem*; *Treponema buccale* Dobell, Arch. f. Protistenk., 26, 1912, 117, *Spironema buccale* Gross, Cent. f. Bakt., I Abt., Orig., 85, 1912, 84; *Spiroschaudinia buccalis* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 450; Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 495; *Treponema inaequale* Brumpt, *ibid.*; *Treponema undulatum* Brumpt, *ibid.*, 514.) From Latin *buccalis*, buccal.

Morphology. 0.4 to 0.9 by 7 to 20 microns. The largest of the mouth spirochetes.

Motility: Active, serpentine, rotating and flexuous.

Staining: Stains with aniline dyes and is violet with Giemsa's stain

Cultivation: Has not been obtained in pure culture and probably does not grow in any medium tried to date.

Habitat: In normal mouths and invades formed lesions of the respiratory mucous membrane.

11. *Borrelia vincenti* (Blanchard) Bergey et al. (*Spirochaeta vincenti* Blanchard, Arch. f. Protistenk., 10, 1906, 129; *Spirochaeta schaudinni* Prowazek, Arb. kaiserl. Gesundheitsamte, 23, 1907, 23; *Spirochaeta plaut-vincenti* Lehmann and Neumann, Bakt. Diag., 5 Aufl., 2, 1912, 579, *Spiroschaudinna vincenti* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 402, *Spiroschaudinna schaudinni* Castellani and Chalmers, *idem*, *Spirochaeta vincenti* Park and Williams, Pathogenic Microorganisms, 6th ed., 1917, 506; *Treponema vincenti* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 514; *Treponema schaudinni* Brumpt, *idem*; Bergey et al., Manual, 2nd ed., 1925, 435.) Named for Vincent, the French bacteriologist.

Morphology. 0.3 by 8 to 12 microns, 3 to 8 irregular shallow spirals. Stains easily with the common aniline dyes and is Gram-negative.

Motility. Has a rapid progressive and vibratory motion.

Cultivation. Can be cultivated under anaerobic conditions. Cultures may show long forms with only a writhing motion.

Not pathogenic for laboratory animals.

Habitat. Found on normal respiratory mucous membrane and is associated with a fusiform bacillus (*Fusobacterium plauti-vincenti*) in Vincent's angina.

12. *Borrelia refringens* (Schaudinn and Hoffmann) Bergey et al. (*Spirochaeta refringens* Schaudinn and Hoffmann, Arbeiten kaiserl. Gesundheitsamte, 22, 1905, 528; *Spirochaeta refringens* Hoffmann and Prowazek, Cent. f. Bakt., 1 Abt., Orig., 41, 1906, 712; *Spirochaeta refringens* Gross, Arch. f. Protistenk., 24, 1912, 115, *Spiroschaudinna refringens* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 459; *Treponema refringens* Castellani and Chalmers, *ibid.*, 461; Bergey et al., Manual, 2nd ed., 1925, 436.) From Latin, refractive.

Morphology: 0.5 to 0.75 by 6 to 20 microns. Spirals are coarse and shallow.

Spirals are generally smoothly rounded and regular, tapering towards the end into a fine projection. Stains easily by common dyes. In stained specimens the spirals appear irregular.

Motility. Active serpentine and rotating motion with marked flexion.

Cultivation. Uncertain.

Pathogenicity. None.

Source. Found with *Treponema pallidum* in some cases of syphilis as originally described by Schaudinn.

Habitat. Genital mucous membranes and necrotic lesions of the genitalia of man.

13. *Borrelia hyos* (King and Drake) Bergey et al. (Hog cholera virus, King and Baeslack, Jour. Inf. Dis., 12, 1913, 39; *Spirochaeta suis* King, Baeslack and Hoffmann, Jour. Inf. Dis., 12, 1913, 235; not *Spirochaeta suis* Bosanquet, Spirochetes, Saunders, 1911, *Spirochaeta hyos* King and Drake, Jour. Inf. Dis., 16, 1915, 54, *Spirochaeta hyos* Bergey et al., Manual, 1st ed., 1923, 426, Bergey et al., Manual, 2nd ed., 1925, 436; *Spirochaeta suis* Ford, Textb. of Bact., 1927, 959.) From Greek, hog.

Morphology. 1 micron by 5 to 7 microns. Distinctly shorter and thicker than other members of the genus.

Motility. Active spinning motion, spirals fixed.

Cultivation. Grows under anaerobic conditions in the presence of tissue.

Habitat. Found in the blood, intestinal ulcers and other lesions of hogs suffering from hog cholera.

14. *Borrelia hermsi* (Davis) Steinhaus. (*Spirochaeta hermsi* Davis, Amer. Assoc. Adv. Sci., Pub. No. 18, 1912, 16; Steinhaus, Insect Microbiology, 1916, 453.)

Investigations by Davis (*loc. cit.*) indicate that each species of *Ornithodoros* that is a relapsing fever vector carries a spirochete that is tick-host specific and that this host specific relationship offers a more accurate approach to the differentiation of relapsing fever spirochetes.

than any of the several criteria previously used.

This was shown to be the case for *Borrelia hermsi* and *Borrelia parkeri*. For this reason no attempt is made to describe the morphology and other characters of the relapsing fever spirochetes of North and South America.

*Borrelia hermsi* is transmitted by *Ornithodoros hermsi*.

A cause of relapsing fever in the Western part of the U. S. A.

15. *Borrelia parkeri* (Davis) Steinhaus. (*Spirochaeta parkeri* Davis, loc. cit.; Steinhaus, loc. cit.)

Transmitted by *Ornithodoros parkeri*.

A cause of relapsing fever in the Western part of the U. S. A.

16. *Borrelia turicatae* (Brumpt) Steinhaus (*Spirochaeta turicatae* Brumpt, Comp. rend. Soc. Biol., Paris, 113, 1933, 1369; Steinhaus, loc. cit.)

Transmitted by *Ornithodoros turicata*.

A cause of relapsing fever in Mexico, Texas and nearby areas.

17. *Borrelia venezuelensis* Brumpt (*Treponema venezuelensis* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1921, 492; Brumpt, *ibid.*, 495; *Spirochaeta venezuelensis* Pettit, Contributions à l'Étude des Spirochétidés, Vanves, 2, 1928, 295)

Transmitted by *Ornithodoros rudis* (*O. venezuelensis*).

A cause of South American relapsing fever.

Brumpt (Précis de Parasitologie, 3rd ed., Paris, 1936) regards this species as identical with *Borrelia neotropicalis* (Bates, Dunn and St John) Steinhaus. (*Treponema neotropicalis* Bates, Dunn and St John, Amer. Jour. Trop. Med., 1, 1921, 183; *Spirochaeta neotropicalis* St John and Bates, Amer. Jour. Trop. Med., 2, 1922, 251; Steinhaus, loc. cit.) Transmitted by *Ornithodoros venezuelensis*. A cause of relapsing fever in Panama.

Appendix: Many of the species included in this appendix are so inadequately described that it is not certain that they belong in this group.

*Borrelia phagedenis* (Nogurhi) Bergey et al. (*Spirochaeta phagedenis* Noguchi, Jour. Exp. Med., 16, 1912, 261; *Spiroschaudinia phagedenis* Castellani and Chalmers, Man. Trop. Med., 2nd ed, 1913, 403; *Treponema phagedenis* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 511; *Spironema phagedenis* Bergey et al., Manual, 1st ed., 1923, 426; Bergey et al., Manual, 2nd ed., 1925, 435.) From phagedenous ulcer.

*Heliconema pyrphoron* Scholer. (Cent. f. Bakt., I Abt., Orig., 138, 1937, 342.) From human blood. Pathogenic.

*Heliconema vincenti* Sanarelli. (Ann. Inst. Past., 41, 1927, 701.) From the intestine of a guinea pig. Shows stages between spirochetes and fusiform bacilli (See Hindle, Med Res Council Syst. of Bact., 3, 1931, 130)

*Microspirionema merlangi* Duboscq and Lebailly. (Compt. rend. Acad. Sci. Paris, 154, 1912, 662) From the whiting, *Merlangus merlangus*. May be a synonym of *Spirochaeta gadi*.

*Spirillum gondii* Nicolle. (Nicolle, Compt. rend. Soc. Biol., Paris, 63, 1907, 213; *Spirochaeta gondii* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., 3, 1931, 1680.) Found in the blood of a rodent, *Ctenodactylus gor.* Not pathogenic. Associated with a piroplasma. Probably not a spirochete.

*Spirillum latapici* Laveran. (Laveran, Bull. Soc. Path. Exot., 1, 1908, 148; *Spirochaeta latapici* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., 3, 1931, 1683; *Spironema latapici* (sic) Ford, Textb. of Bact., 1927, 964.) From the blood of a shark.

*Spirillum pitheci* Thiroux and Dufourgeré. (Thiroux and Dufourgeré, Compt. rend. Acad. Sci. Paris, 150, 1910, 132; *Spirochaeta pitheci* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., 3, 1931, 1676; *Spironema pitheci* Ford,

Textb. of Bact., 1927, 961.) From the blood of an African monkey, *Cercopithecus patas*. Pathogenic for monkeys, rats and field mice. Closely related to *Borrelia duttoni*.

*Spirochaeta aboriginalis* Cleland (Cleland, Jour. Trop. Med., 12, 1909, 143, *Spiroschaudinna aboriginalis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 402, *Treponema aboriginalis* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 493.) Found in cases of granuloma inguinale in West Australia. Probably saprophytic.

*Spirochaeta acuminata* Castellani (Castellani, Brit. Med. Jour., 2, 1905, 1330, *Spirochaeta tenuis acuminata* Castellani, *idem* and/or Arch. f. Schiffshygiene Tropenhyg., 12, 1908, 311; *Spiroschaudinna acuminata* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 449, *Treponema acuminatum* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 495.) From ulcerated lesions of yaws.

*Spirochaeta acuta* Kritchewski and Séguin (Rev. de Stomatol., 22, 1920, 613.) From the oral cavity.

*Spirochaeta aeglefini* Henry (Jour. Path. and Bact., 18, 1913, 222.) From haddock.

*Spirochaeta aegyptica* Gonder (Gonder, in Prowazek, Handb. d. path. Protoz., 8, 1914, 671; *Spirochaeta aegyptica* Noguchi, Jour. Exp. Med., 27, 1918, 581, *Treponema aegypticum* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 500, *Borrelia aegypticum* Steinhaus, Insect Microbiology, 1916, 452.) Observed in cases of relapsing fever in Sudan. Probably a synonym of *Borrelia recurrentis*.

*Spirochaeta ambigua* Séguin and Vincent (Séguin and Vincent, Compt. rend. Soc. Biol., Paris, 121, 1936, 408, *Treponema ambigua* Prévot, Man. Class. et Determ. d. Bactéries Anaérobies, Paris, 1910, 293.) From the oral cavity and the lungs. Pathogenic. Strict anaerobe.

*Spirochaeta amphibiae* Yakimoff and Müller. (Bull. Soc. Path. Exot., 18, 1923,

306.) From the intestines of frogs, *Rana temporaria*.

*Spirochaeta argentinensis* Kuhn and Steiner. (Kuhn and Steiner, Med. Klin., 13, 1917, 1007; *Spirochaeta polysclerotica* Arzt and Kerl, according to Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 134; *Treponema* (?) *argentinensis* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 478.) From the livers of guinea pigs and rabbits inoculated with blood from patients having multiple sclerosis. Pathogenic for man, monkeys, dogs, rabbits and guinea pigs. Named for the Latin name of the town of Strasbourg (*Argentoratum*).

*Spirochaeta balanitidis* Hoffmann and Prowazek (Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., 41, 1906, 741; *Spiroschaudinna balanitidis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 401, *Spirochaeta balanitidis* Park and Williams, Pathogenic Microorganisms, 6th ed., 1917, 505; *Treponema balanitidis* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 496.) From a case of balanitis.

*Spirochaeta boris-caffris* Nuttall. (Nuttall, Parasitology, 3, 1910, 108; *Spirochaeta boris-caffris* Ford, Textb. of Bact., 1927, 960.) From the blood of a buffalo.

*Spirochaeta bronchialis* Castellani (Castellani, Ceylon Medical Reports, 1907; *Spiroschaudinna bronchialis* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 402, *Treponema bronchiale* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 496.) Found in cases of bronchitis in Ceylon. A mixture of several species of mouth spirochaetes is apparently described under this designation.

*Spirochaeta bucco-pharyngei* Macfie. (Macfie, Ann. Trop. Med. and Parasitol., 10, 1916, 329, *Treponema bucco-pharyngei* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 497.) From the throat of a native of the Gold Coast. May be identical with *Spirochaeta dentium* or *S. buccalis*.

*Spirochaeta bufonis* Dobell. (Dobell, Quart. Jour. Microsc. Sci., 52, 1908, 121; *Spiroschaudinna bufonis* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 454; *Spirochaeta bufonis* Ford, Textb. of Bact., 1927, 986; *Treponema bufonis* Ford, *ibid.*) From the intestines of a toad, *Bufo vulgaris*.

*Spirochaeta caesirae retortiformis* Hellmann. (Arch. f. Protistenk., 29, 1913, 22.) From the urinary sac of a tunicate, *Caesira retortiformis*.

*Spirochaeta caesirae septentrionalis* Hellmann. (Arch. f. Protistenk., 29, 1913, 22.) From the urinary sac of a tunicate, *Caesira septentrionalis*.

*Spirochaeta canina* Bossclut. (Bull. Soc. Path. Exot., 18, 1925, 702.) From the blood of a dog.

*Spirochaeta canis* Macfie. (Ann. Trop. Med. and Parasitol., 10, 1916, 305.) From dog feces.

*Spirochaeta cobayae* Knowles and Basu (Knowles and Basu, Indian Jour. Med. Res., 22, 1935, 449; *Treponema cobayae* Topley and Wilson, Princip. Bact. and Immun., 2nd ed., 1936, 725; *Borrelia cobayae* Steinhaus, Insect Microbiology, 1946, 454.) From the blood of guinea pigs. Blood parasite belonging to the relapsing fever group. Pathogenic for guinea pigs, rabbits and white rats.

*Spirochaeta comandoni* Séguin and Vincent. (Séguin and Vincent, Compt. rend. Soc. Biol., Paris, 121, 1936, 403; *Treponema comandoni* Prévot, Man. Class. et Determ. d. Bactéries Anaérobies, Paris, 1940, 208.) From the oral cavity. Rather common. Non-pathogenic. Strict anaerobe.

*Spirochaeta crocidurae* Leger (Leger, Bull. Soc. Path. Exot., 10, 1917, 280; *Treponema crocidurae* McFarland, Pathogenic Bacteria and Protozoa, 2nd ed., 1933, 136.) From a shrew-mouse, *Crocidura stamplii*, in Senegal. Transmitted by *Ornithodoros erraticus*.

*Spirochaeta ctenocephali* Patton. (Patton, Ann. Trop. Med. and Parasitol., 6, 1912, 357; *Treponema ctenocephali* Ford, Textb. of Bact., 1927, 989.) Para-

sitic in the digestive tract of the larvae of the Indian cat-flea, *Ctenocephalus felis*.

*Spirochaeta cubensis* Hoffman. (Sanidad y Beneficiencia Boletín oficial, Havana, 28, 1923, 76.) From the feces of *Hyla septentrionalis*.

*Spirochaeta culicis* Jaffé. (Jaffé, Arch. f. Protistenk., 9, 1907, 100; *Spirochaeta culicis* Gross, Cent. f. Bakt., I Abt., Orig., 65, 1912, 87; *Entomospira culicis* Enderlein, Sitzungsber. Ges. Naturf. Freunde, Berlin, 1917, 313; *Spiroschaudinna culicis* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 454; *Spirillum culicis* Pringault, Compt. rend. Soc. Biol., Paris, 84, 1921, 209; *Treponema culicis* Ford, Textb. of Bact., 1927, 989.) Found in the intestines and Malpighian tubules of mosquito larvae, *Culex* sp.

*Spirochaeta didelphis* Vianna, de Figueiredo and Cruz. (Brasil-Médico, 26, 1912, 912.) From the blood of an opossum, *Didelphis aurita*.

*Spirochaeta equi* (Novy and Knapp) Castellani and Chalmers. (*Spirillum equi* Novy and Knapp, Jour. Inf. Dis., 3, 9106, 294; Castellani and Chalmers, Man. Trop. Med., 1st ed., 1910, 309; *Spiroschaudinna equi* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 404; *Spirochaeta equi* Noguchi, Jour. Exp. Med., 27, 1918, 584; *Treponema equi* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461.) From the blood of a horse. May be identical with *Borrelia theileri*.

*Spirochaeta equina*. (Dodd ?, Jour. Comp. Pathol. and Therap., 19, 1906, 318; quoted from Pettit, Contribution à l'Étude des Spirochétidés, Vanves, 11, 1928, 111.)

*Spirochaeta eurygyrata* Werner (Werner, Cent. f. Bakt., I Abt., Orig., 52, 1909, 241; *Spirochaeta eurygyrata* (sic) Noguchi, Jour. Exp. Med., 27, 1918, 584; *Spiroschaudinna eurygyrata* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 451; *Spirillum eurygyrata* Castellani and Chalmers, *ibid.*; *Borrelia eury-*

*gyrata* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 495; *Treponema eurygyratum* Brumpt, *ibid.*, 50 ) From the intestinal contents of man.

*Spirochaeta exanthematotryphi* Futaki (Futaki, Brit Med Jour, Oct 13, 1917; *Treponema exanthematotryphi* Salvini, Compt rend. Soc Biol, Paris, 88, 1923, 958 ) Found in the kidneys and urine of cases of exanthematous typhus Non-pathogenic.

*Spirochaeta febris* Chester (Afanasiew, Cent. f. Bakt, I Abt., 25, 1899, 405, Chester, Man Determ. Bact., 1901, 347 ) From a case of recurrent fever

*Spirochaeta gadi* Neumann (Neumann, Ztschr. f Hyg, 64, 1909, 79; *Microspironema gadi* Duboscq and Lebaully, Compt. rend Acad Sci Paris, 154, 1912, 662, *Treponema gadi* Duboscq and Lebaully, Arch. zool. expér. et génér, 10, 1912, 331; *Spironema gadi* Ford, Textb. of Bact., 1927, 961 ) From the blood of a sea fish, *Gadus minutus*

*Spirochaeta gallica* Couvy and Dujarric de la Rivière. (Couvy and Dujarric de la Rivière, Compt rend Soc Biol, Paris, 81, 1918, 22, *Treponema gallicum* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 500 ) From the blood of trench fever patients

*Spirochaeta gangraenae carcinomatosa* Hoffmann. (Berl klin Wochenschr, 42, 1905, 880.) From malignant tumors.

*Spirochaeta gangraenosa nosocomialis* Róna (Róna, Verhandl d deutsch dermat Gesellsch, 9, 1907, 471, *Treponema gangraenosa nosocomialis* Noguchi, Jour Exp Med, 16, 1912, 261 ) From ulcers of the genital region.

*Spirochaeta haemophilus* Trosier and Sifferlen. (Ann Inst Past, 58, 1917, 223 ) From a child with intestinal trouble and continuous fever

*Spirochaeta hispanica* de Buen (De Buen, Ann Parasitol., 4, 1926, 183; *Treponema hispanicum* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun, 1928, 481, *Spirochaeta marocanum* Nicolle and Anderson, Compt. rend Acad Sci Paris, 157, 1923, 747; Amer. Med. Assoc., 42, 1907, 198 8;

*Spirochaeta hispanicum* var. *marocanum* Nicolle, Anderson and Colas-Belcour, Arch. Inst Past Tunis, 18, 1929, 343; *Treponema hispanicum* var. *marocanum* Gay et al, Agents of Disease and Host Resistance, 1935, 1074; *Borrelia hispanicum* Steinhaus, Insect Microbiology, 1916, 453 ) The cause of Spanish and Moroccan relapsing fever Transmitted by *Ornithodoros marocanus* Not agglutinated by serum of *Borrelia recurrentis*. Pathogenic for man and laboratory animals

*Spirochaeta intestinalis* Macfie and Carter (Macfie and Carter, Ann Trop Med and Parasitol, 11, 1917, 79, *Treponema intestinale* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 503 ) From human feces.

*Spirochaeta jonessi* Dutton, Todd and Tobey (Dutton, Todd and Tobey, Jour Med Res, 15 (N.S. 10), 1906, 491; *Spironema jonessi* Ford, Textb. of Bact., 1927, 964 ) From the blood of an African mudfish, *Clarias angolensis*

*Spirochaeta lagopodis* Fantham. (Fantham, Proc Zool. Society, London, 1910, 692, *Spironema lagopodis* Noguchi, according to Pettit, *loc. cit* ) From the blood of the grouse, *Lagopus scoticus*.

*Spirochaeta leucotermis* Hollande. (Arch. zool. expér. et gén., 61, 1922, 23 ) From an insect, *Leucotermes lucifugus*.

*Spirochaeta lorati* Fantham. (Proc Zool Society, London, 1910.) From the intestinal contents of the grouse, *Lagopus scoticus*

*Spirochaeta lourentzalis* Besson (Besson, p. 736, according to Ford, Textb. of Bact, 1927, 1001.) From malignant tumors

*Spirochaeta lutrae* Prowazek. (Prowazek, Arb. Kaiserl Gesundheitsamte, 26, 1907, 31, *Spiroschaudinia lutrae* Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 401; *Spironema lutrae* Ford, Textb. of Bact., 1927, 961.) From the blood of an otter, *Lutra* sp.

*Spirochaeta lymphaticus* Proeschner and White. (Proeschner and White, Jour. Amer. Med. Assoc., 42, 1907, 198 8;

1925, 306.) From the intestines of frogs, *Rana temporaria*.

*Spirochaeta tenuis* Gerber. (Gerber, Cent. f. Bakt., I Abt., Orig., 56, 1910, 508; *Treponema tenue* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 514.) May be identical with *Spirochaeta dentium* or with *Borrelia vincentii*.

*Spirochaeta termittis* (Leidy) Dobell. (*Vibrio termittis* Leidy, Jour Acad. Nat. Sci., Phila., 2nd Ser., 8, 1881, 441; *Spirochaeta minei* Prowazek, Arch. f. Schiffsu. Tropenhyg., 14, 1910, 297; Dobell, *Spolia ceylanica*, 3, 1910, 78; *Treponema minei* Dobell, *ibid*; ? *Spirochaete grassii* Doflein, Prob. der Protistenk., 2, 1911, 17; *Spirochaeta grassii* Döflein, Die Natur der Spirochäten, Jena, 1911; *Treponema termittis* Dobell, Arch. f. Protistenk., 28, 1912, 117; *Entomospira grassii* Enderlein, Sitzungsber. Ges. Naturf. Freunde, Berlin, 1917, 313; *Cristispira termittis* Hollande, Arch. Zool. Expér. et Gén., 61, 1923, N. and R., 25; *Treponema grassii* Ford, Textb. of Bact., 1927, 988.) From the intestines of *Termes lucifugus* and *Calotermes* spp.

*Spirochaeta tropidonoti* Dobell. (Dobell, *Spolia ceylanica*, 7, 1911, 65, *Spirochaeta tropidonoti* Ford, Textb. of Bact., 1927, 962.) Isolated once from the blood of a snake, *Tropidonotus stolatus*, in Ceylon.

*Spirochaeta urethrae* Macfie. (Macfie, Ann. Trop. Med. and Parasitol., 10, 1916, 305; *Spiroschaudinna urethrae* Castellani and Chalmers, Man Trop Med, 3rd ed., 1919, 451; *Treponema urethrae* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 514.) From the urine of Gold Coast natives. Causes acute arthritis.

*Spirochaeta usbekistanica* Pickoul. (Russ. Jour Trop Med, 6, 1928, 612.) From cases of relapsing fever in Bokhara.

*Spirochaeta vespertilionis* (Novy and Knapp) Castellani and Chalmers (*Spirillum vespertilionis* Novy and Knapp, Jour Inf. Dis, 3, 1906, 291, Castellani and Chalmers, Man Trop Med, 1st ed., 1910, 309; *Spiroschaudinna vespertilionis* Castellani and Chalmers, Man Trop.

Med., 3rd ed., 1919, 454; *Spirochaeta vespertilionis* Ford, Textb. of Bact., 1927, 961.) From the blood of a bat, *Vesperugo kuhlii*.

*Spirochaeta vincentii* var. *bronchialis* Delamare. (Compt. rend. Soc. Biol., Paris, 90, 1924, 611.)

*Spirochaeta zlatogorovi* Yakimoff. (Bull. Soc. Path. Exot., 14, 1921, 532.) From feces.

*Spirochaeta exanthematica* Lewascheff. (Cent. f. Bakt., I Abt., 18, 1895, 133.) From the blood in cases of typhus fever.

*Spirochaete forans* Reiter. (Reiter, Deutsch. med. Wochenschr., No. 50, 1916, 10; see Cent. f. Bakt., I Abt., Orig., 79, 1917, 176; *Treponema forans* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 500; *Spirochaeta forans* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 164.) From the blood in a case of articular rheumatism. Not pathogenic for guinea pigs or mice.

*Spirochaeta gracilis* Veszpremi. (Veszpremi, Cent. f. Bakt., I Abt., Orig., 44, 1907, 333; not *Spirochaeta gracilis* Levaditi and Stanesco, Compt. rend. Soc. Biol., Paris, 67, 1903, 188 (*Treponema levaditii* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 501; *Treponema gracile* Brumpt, *idem*); *Treponema gracile* Ford, Textb. of Bact., 1927, 976.) From a gangrenous phlegmon of the mouth. Found in association with fusiform bacilli and therefore may be identical with *Borrelia vincentii* or *Spirochaeta dentium* or *Treponema macrodentium*.

*Spirochaete repacis*. (Quoted from Lehmann and Neumann, Bakt. Diag., 6 Aufl., 2, 1920, 809.) From the oral cavity.

*Spirochaeta cariae* Ford (*Spirochaete* (?), Macfie, Ann. Trop. Med. and Parasitol., 8, 1914, 447; Ford, Textb. of Bact., 1927, 961.) From the blood of a guinea pig at Lagos.

*Spirochaeta vesperuginis* (Gonder) Ford. (*Spirochaeta vesperuginis* Gonder, Arb. kais. Gesundheitsamte, 27, 1908, 406; Ford, Textb. of Bact., 1927, 961.) From the blood of a bat, *Vesperugo kuhlii*.

*Spiroschaudinna cariae* Sangiorgi.

- 39. *Pseudomonas ambigua*.
- 40. *Pseudomonas sinuosa*.
- 41. *Pseudomonas cruciviae*
- cc. Grow poorly or not at all at 37°C.
  - d. Action on hydrocarbons and cellulose unknown
    - 42. *Pseudomonas rugosa*
  - dd. Utilize hydrocarbons.
    - 43. *Pseudomonas desmolyticum*.
    - 44. *Pseudomonas rathonis*.
    - 45. *Pseudomonas dacunhae*.
    - 46. *Pseudomonas arvilla*
    - 47. *Pseudomonas salopium*.
  - ddd Utilize cellulose.
    - 48. *Pseudomonas minuscula*.
    - 49. *Pseudomonas translucida*
    - 50. *Pseudomonas mira*
- aaa. Action on gelatin not recorded Produces alcoholic fermentation of glucose
  - 51. *Pseudomonas lindneri*
- Sea water to brine species. Some species phosphorescent
  - a Gelatin liquefied.
  - b. Polar flagellate
    - c From sea water. Not deeply pigmented.
      - d Nitrites not produced from nitrates.
        - 52. *Pseudomonas membranoformis*.
        - 53. *Pseudomonas marinoglutinosa*
      - dd. Nitrites produced from nitrates so far as known
        - e. Digest agar.
          - 54. *Pseudomonas gelatica*.
      - ee Deposit calcium carbonate in sea water gelatin and agar media in old cultures
        - 55. *Pseudomonas calcis*.
        - 56. *Pseudomonas calciprecipitans*
      - eee Causes skin lesions in marine fish.
        - 57. *Pseudomonas ichthyodermis*
  - cc. Produce highly colored pigments in media containing salt or in heavy brines.
    - d. Blackens salted butter.
      - 58. *Pseudomonas nigrificans*
    - dd. Causes purple discoloration of salted beans.
      - 59. *Pseudomonas beyerinckii*.
    - ddd. Reddens heavy brines (more than 18 per cent salt).
      - 60. *Pseudomonas salinaria*
      - 61. *Pseudomonas culirubra*
  - ccc. Phosphorescent bacteria from decaying fish and crustaceans, and phosphorescent organs of sea animals.
    - d. Gelatin liquefied.
      - 62. *Pseudomonas harveyi*.
    - dd Gelatin not liquefied.
      - 63. *Pseudomonas phosphorescens*.
      - 64. *Pseudomonas pierantoni*.

Morphologically indistinguishable from *Treponema pallidum*.

Cultivable under anaerobic conditions in the same medium used for *Treponema pallidum*.

Habitat: The cause of yaws—tropical frambesia. Patients with the disease give a positive Wassermann test. Probably transmitted by contact.

3. *Treponema microdentium* Noguchi. (Jour. Exp. Med., 15, 1912, 81.) From Greek *mikros*, small and Latin, teeth.

The organism is less than 0.25 micron in thickness in the middle and tapers toward each extremity, which is pointed. The length varies with age but may reach 8 microns and show an average of 14 curves. Sometimes a long, thin flagella-like projection is observed at each extremity.

Growth occurs under anaerobic conditions in serum water medium containing fresh tissue. The serum is slightly coagulated and gives off a strong, fetid odor.

Habitat: Normal oral cavity.

4. *Treponema mucosum* Noguchi. (Jour. Exp. Med., 16, 1912, 194; *Spirochaeta mucosa* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 190.) From Latin, mucous

Spirals: 0.25 to 0.3 by 8 to 12 microns. The number of curves varies from 6 to 8. Both extremities are sharply pointed and often possess a minute curved projection, 8 to 10 microns long.

Cultivable under anaerobic conditions, forming mucin.

The cultures give off a strong, putrid odor.

Takes the red in Giemsa's stain

Strict anaerobe.

Source: From pus in a case of pyorrhoea.

Habitat: Found in pyorrhea alveolaris. It possesses pyogenic properties.

5. *Treponema calligyrum* Noguchi. (Noguchi, Jour. Exp. Med., 17, 1913, 96; *Spirochaeta calligra* Zuelzer, 1925, in Prowazek, Hand. d. path. Protoz., 5, 1931,

1673.) From M. L., with beautiful circles.

Morphology: 0.35 to 0.4 by 6 to 14 microns, average 9 to 12 microns. Spirals are regular and deep but more rounded than those of *Treponema pallidum*. The organism is of uniform width until near the extremities which end in sharp points with delicate projections.

Motility: Active, chiefly rotating.

Stains reddish-violet with Giemsa's stain.

Cultivation: Grows under anaerobic conditions.

Not pathogenic for monkeys or rabbits.

Source: From smegma.

Habitat: Lesions and membranes of the pudenda.

6. *Treponema genitalis* Noguchi (*Treponema minutum* Noguchi, Jour. Exp. Med., 27, 1918, 671; not *Treponema minutum* Dobell, Arch. f. Protistenk., 26, 1912, 151; not *Treponema minutum* Castellani, 1916; Noguchi, Laboratory Diagnosis of Syphilis, New York, 1923, 260; *Spirochaeta minutum* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., 5, 1931, 1673; *Spirochaeta genitalis* Séguin and Vincent, Ann. Inst. Past., 61, 1933, 255) From Latin, genital.

Morphology: 0.25 to 0.3 by 3 to 14 microns. Spirals round, regular and shallow. Smaller than *Treponema pallidum* and spirals are closer to each other.

Motility: Active

Culture: Grows anaerobically and requires fresh tissue

Non pathogenic.

Habitat: Found on male and female genitalia.

7. *Treponema carateum* Brumpt. (*Treponema* de un caso de piata, Saenz, Grau Triana and Alfonso, Arch. de Med. Int., Havana, 4, 1933, 3; Brumpt, Compt. Rend. Soc. Biol., Paris, 130, 1939, 912; *Treponema herrejoni* León y Blanco, Rev. de Med. Trop. y Parasitol., Habana, 6, 1940, 5, *Treponema pictor* Pardo-Castello, Rev. de Med. Trop. y Parasitol.

(Sangiorgi, Pathologica Rivista, 5, 1913, 428; *Spirochaeta caviae* Hindle, Med. Res. Council Syst. of Bact., 8, 1931, 174.) From the blood of a guinea pig

*Spiroschaudinna mitis* Castellani and Chalmers. (Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 451; *Treponema mite* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 506.) From

urine in mild cases of camp jaundice. Probably not pathogenic.

*Treponema lincola* (Donné) Brumpt. (*Vibrio lincola* Donné, Recherches Microsc. Nature d. Mucus des Organes Génitourinaires, Paris, 1837; Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 505) From secretions of the genitalia.

## Genus II. *Treponema* Schaudinn.

in acute, regular or irregular spirals Terminal filament may be present. Some species stain only with Giemsa's stain. Weakly refractive by dark field illumination in living preparations Cultivated under strictly anaerobic conditions. Pathogenic and parasitic for man and animals Generally produce local lesions in tissues.

The type species is *Treponema pallidum* (Schaudinn and Hoffmann) Schaudinn.

1 *Treponema pallidum* (Schaudinn and Hoffmann) Schaudinn. (*Spirochaete pallida* Schaudinn and Hoffmann, Arb. kaiserl. Gesundheitsamte, 22, 1905, 528; Schaudinn, Deutsche med. Wochenschr., 31, 1905, 1728; *Spirochaeta pallidum* Vuillemin, Compt. rend. Acad. Sci. Paris, 140, 1905, 1567; *Microspirochaeta pallidum* Stiles and Pfender, Amer. Med., 10, 1905, 936; *Trypanosoma luis* Krzystalowicz and Siedlecki, 1905, see abstr. in Bull. Inst. Past., 4, 1906, 204; *Spirochaeta pallida* Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., 41, 1906, 741.) From Latin, pale.

Morphology: Very fine protoplasmic spirals 0.25 to 0.3 by 6 to 14 microns

Spiral amplitude: 1.0 micron, regular, fixed

Spiral depth: 0.5 to 1.0 micron.

Terminal spiral filament present

Weakly refractive in living state by dark field illumination. May appear as a series of bright dots or string of radiant beads with poor dark field illumination.

Staining: Stain with difficulty except with Giemsa's stain by which they appear pink or rose. Appear black with silver impregnation methods

Motility: Sluggish, drifting motion, stiffly flexible, rarely rotating

Trypsin digestion: Resistant for many days

Bile salts (10 per cent): Disintegration complete

Saponin (10 per cent): Broken up in time

Cultivation: With difficulty under strict anaerobiosis in ascitic fluid with addition of fresh rabbit kidney.

Habitat: The cause of syphilis in man. Can be transmitted experimentally to anthropoid apes and rabbits

2 *Treponema pertenue* Castellani. (Castellani, Jour. Trop. Med., 8, 1905, 253; *Spirochaeta pertenue* Castellani, Jour. Ceylon Branch Brit. Med. Assoc., June, 1905; *Spirochaeta pallidula* Castellani, Brit. Jour. Med., 2, Nov., 1905, 1330; *Spirochaete pertenue* Lehmann and Neumann, Bakt. Diag., 5 Aufl., 2, 1912, 677; *Spirochaeta pertenue* Gross, Archiv f. Protistenk., 24, 1912, 115; *Treponema pallidulum* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 508) From Latin, very fine.

Habana, C, 1910, 117; *Treponema pintae* Curbelo, Elementos de Bacteriología Médica, 1941, 34.) From carate, spotted sickness

Description taken from León y Blanco (*loc. cit.*)

Cylindrical 0.25 to 0.30 by 7.8 to 30.8 microns, average length 17.8 microns. With sharp-pointed ends.

Spiral amplitude 1 micron, regular

Spiral depth 0.8 to 1.0 micron.

Number of waves, 6 to 27, according to length. Ten to twelve (Brumpt, *loc. cit.*)

Actively motile. At times undulating or creeping movements are shown

Staining reactions. Readily takes silver impregnations, Giemsa's stain, carbol-fuchsin and gentian violet

Saponin (10 per cent) Disintegrates in six hours at room temperature. Same result with sodium taurocholate (10 per cent) and with bile.

Distilled water. Produces swelling

Loses motility on heating for 15 minutes at 50°C or for 3 hours at 41°C.

Wassermann, Kahn and Meinicke reactions positive

Has not yet been cultivated artificially. Experimental transmission unsuccessful so far.

Source. From the border of cutaneous lesions of persons having pinta (spotted sickness)

Habitat. The cause of pinta (or carate). Common in Mexico and Colombia. Also found in other northern countries of South America, in Central America and the West Indies. Rare in Cuba. Possibly found in other tropical regions of the world

8 *Treponema cuniculi* Noguchi (*Spirochaeta paralus cuniculi* Jakobthal, Dermatol. Wehnschr., 71, 1920, 569; Noguchi, Jour. Amer. Med. Assoc., 77, 1921, 2352, also see Noguchi, Jour. Exp. Med., 33, 1922, 317; *Treponema pallidum* var. *cuniculi* Klatsenbeek, Cent. f. Bakt. 1 Abt., Orig., 87, 1921, 283; *Spirochaeta cuniculi* Sorditi, Marie and Isuen,

Compt. rend. Soc. Biol., Paris, 85, 1921, 51; *Spirochaeta pallida* var. *cuniculi* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., 3, 1931, 1765; *Spirochaeta paralus* Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 91; *Spirochaeta paralus-cuniculi* Hindle, Med. Res. Council Syst. of Bact., 8, 1931, 187.) From Latin, rabbit.

Description from Noguchi (*loc. cit.*)

Closely resembles *Treponema pallidum*, but longer.

Width 0.25 micron; length 10 to 16 microns; long specimens up to 30 microns frequent.

Spirals 8 to 12 in number, regular, deep.

Spiral amplitude 1 to 1.2 microns

Spiral depth 0.6 to 1.0 micron.

Delicate terminal filament at one, sometimes both, ends

Often forms entangled masses of long threads, occurs sometimes in a stellate arrangement

Staining properties same as for *Treponema pallidum*. Both readily stained by ordinary basic aniline dyes when fixed in a buffered formaldehyde solution

Wassermann reaction negative

Pathogenesis. Disease transmissible to healthy rabbits, producing papular lesions in the genitoperineal region. Not pathogenic for monkeys, mice or guinea pigs

Source. From lesions in the genitoperineal region of five rabbits

Habitat. The cause of rabbit spirochetosis

Appendix: Many of the species in this appendix are so inadequately described that it is not certain that they belong in this group

*Microspironema legeri* Duloseq and Lebaillly (Duloseq and Lebaillly, Compt. rend. Acad. Sci. Paris, 154, 1912, 162; *Treponema legeri* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., 3, 1931, 1683) From a fish, *Barboopa*.

*Spirochaeta microgyrata* Leewenthal (Leewenthal, Berl. Min. Wehnschr., 43, 1906, 283; *Spirochaeta microgyrata* Nogu-

1928, 911.) Pathogenic. Cause of a disease in sheep.

*Treponema querquedulae* Lebaillly. (Compt. rend. Soc. Biol., Paris, 75, 1913, 389.) From caeca of birds. Named for the teal, *Querquedula querquedula*.

*Treponema rhinopharyngeum* Brumpt. (*Treponema minutum* Castellani, 1916; *Spirochaudinnia minuta* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 1881; Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 514) From man in cases of rhinopharyngitis. Probably a synonym of *Spirochaeta gracilis*.

*Treponema rigidum* Zinsser and Hopkins (Jour. Bact., 7, 1916, 489.) From the tissues in five different strains of rabbit syphilis. Probably a synonym of *Treponema cuniculi*.

*Treponema spermiformis* Duboscq and Grassé (Arch. Zool. Expér et Gén., 66, 1927, 483) From the rectum of a termite, *Glyptotermes iridipennis*.

*Treponema squatarolae* Lebaillly. (Compt. rend. Soc. Biol., Paris, 75, 1913, 389) From the caecum of a bird, *Squatarola squatarola*.

*Treponema stylopygae* Dobell. (Dobell, Arch. f. Protistenk., 26, 1912, 117; *Spirochaeta stylopygae* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., 3, 1931, 1685.) From the intestines of the cockroach, *Stylopyga orientalis*.

*Treponema tricallo* Cohn. (Cohn, 1872, quoted from Castellani and Chalmers, Man. Trop. Med., 2nd ed., 1913, 414.)

*Treponema triglae* Duboscq and Lebaillly. (Arch. Zool. Expér et Gén., 10, 1912, 331.) From the rectum of a fish, *Trigla lucerna*.

*Treponema tropiduri* Neiva, Marques da Cunha and Travassus. (Mem. do Inst. Oswaldo Cruz, 6, 1914, 180.) From the blood of a South American lizard, *Tropidurus torquatus*.

The following species are listed in the index of Castellani and Chalmers, Manual of Tropical Medicine, 2nd ed., 1913, 1718-1719, but are not mentioned in the text (pp. 136-141): *Treponema bovidae*, *T. camelidae*, *T. canidae*, *T. felidae*, *T. hippopotami*, *T. reptilia*, *T. rhinoceri*, *T. sclachii*, *T. suidae*, *T. ungulata* and *T. ursidae*.

### Genus III *Leptospira* Noguchi.

(Jour. Exp. Med., 25, 1917, 753.)

Finely coiled organisms 6 to 20 microns in length. Spirals 0.3 micron in depth and 0.4 to 0.5 micron in amplitude. In liquid medium one or both ends are bent into a semicircular hook each involving  $\frac{1}{10}$  to  $\frac{1}{4}$  of the organism. Spinning movements in liquid and vermiform in semisolid agar, forward or backward. Seen in living preparations only with dark field. Stain with difficulty except with Giemsa's stain and silver impregnation. Require oxygen for growth.

The type species is *Leptospira icterohaemorrhagiae* (Inada and Ido) Noguchi.

1. *Leptospira icterohaemorrhagiae* (Inada and Ido) Noguchi. (*Spirochaeta icterohaemorrhagiae* Inada and Ido, Tokyo Ijishinski, 1915, Inada, Ido, Hoki, Kaneko and Ito, Jour. Exp. Med., 23, 1916, 377; *Spirochaeta icterogenes* Uhlenhuth and Fromme, Med. Klin., 11, 1915, 1202, *Spirochaeta nodosa* Huebner and Reiter, Deutsch. med. Wochenschr., 41, 1915, 1275; Noguchi, Jour. Exp. Med., 25, 1917,

755, *Spirochaudinnia icterohaemorrhagiae* Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 447; *Treponema icterogenes* Gonder and Gross, Arch. f. Protistenk., 32, 1919, 62; *Spirochaeta ictero-haemorrhagica* (sic) Lehmann and Neumann, Bakt. Diag., 6 Aufl., 2, 1929, 810; *Treponema ictero-haemorrhagiae* (sic) Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 501; *Treponema nodosum*

180, *Spirochaeta denticola* Flugge, Die Mikroorganismen, 2 Aufl., 1886, 390; *Spirochaeta dentium* Miller, Microorganisms of the Human Mouth, Philadelphia, 1890, 80, *Spirillum dentium* Sternberg, Manual of Bact., 1893, 691; *Spirochaeta dentium* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 35, *Spirochaeta denticola* Arndt, according to Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., 41, 1906, 819; Dobell, Arch. f. Protistenk., 26, 1912, 117, *Spirochaeta dentium* Gross, Cent. f. Bakt., I Abt., Orig., 65, 1912, 83, *Spirochaeta dentium* McFarland, Pathogenic Bacteria and Protozoa, 7th ed., 1912, 516, *Treponema microdentium* Noguchi, Jour. Exp. Med., 15, 1912, 81, *Spirochaeta orthodonta* Hoffmann, Deutsch. med. Wochenschr., 46, 1920, 257, *Spirochaeta microdentium* Heim, Lehr. d. Bakt., 6 and 7 Aufl., 1922, 477, *Treponema denticola* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 497, *Treponema orthodontum* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 481; *Treponema dentium-stenogyratum* Pettit, Contribution à l'étude des Spirochétidés, Vanves, II, 1928, 210. The smallest of the mouth spirochaetes. Non pathogenic. This term probably includes several morphologically similar species which have not as yet been sufficiently characterized.

*Treponema drosophilae* Chatton (Compt. rend. Soc. Biol., 75, 1912, 212.) From *Drosophila confusa*. Six to thirty microns in length, tapers at both ends, four spirals, movement helicoidal.

*Treponema gallicolum* Lebailluy (Compt. rend. Soc. Biol., Paris, 75, 1913, 389.) From the caecum of the hen, *Galus* sp.

*Treponema hilli* Duboscq and Gras-é (Compt. rend. Soc. Biol., Paris, 94, 1926, 34; Arch. Zool. Expér. et Gén., 66, 1927, 481.) From the surface of the body of a flagellate, *Devescovina hilli*, and in the intestine of a termite, *Glyptotermes rufipennis*. A very small organism.

*Treponema intermedium* Dobell. (Mittelformen, Lühe, Handb. d. Tropen-

krankh., 3, 1906, see Hoffmann and Prowazek, Cent. f. Bakt., I Abt., Orig., 41, 1906, 819, Dobell, Arch. f. Protistenk., 26, 1912, 117, *Treponema macrodentium* Noguchi, Jour. Exp. Med., 15, 1912, 81; *Spirochaeta media oris* Hoffmann, Deutsch. med. Wochenschr., 46, 1920, 257; *Treponema medium* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 505; *Spirochaeta intermedia* Pettit, Contribution à l'étude des Spirochétidés, Vanves, II, 1928, 146, *Spirochaeta macrodentium* Pettit, *ibid.*, 182, *Spirochaeta media* and *Spirochaeta media* Pettit, *ibid.*, 210.) The middle-sized spirochete of the mouth.

*Treponema larsi* Lebailluy. (Compt. rend. Soc. Biol., Paris, 75, 1913, 389.) Found in the caecum of birds, also in the guinea-pig. Named for one of the birds, *Larus ridibundus*.

*Treponema minutum* Dobell. (*Treponema* sp. Dobell, Quart. Jour. Microsc. Sci., 52, 1908, 121, Dobell, Arch. f. Protistenk., 26, 1912, 151, not *Treponema minutum* Castellani, 1916; not *Treponema minutum* Noguchi, Jour. Exp. Med., 27, 1918, 671, *Spirochaeta minutum* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., 3, 1931, 1682.) From the large intestines of toads, *Bufo vulgaris*.

*Treponema parvum* Dobell (Dobell, Arch. f. Protistenk., 26, 1912, 117; *Spirochaeta parvum* Zuelzer, 1925, in Prowazek, Handb. d. path. Protoz., 3, 1931, 1685.) From the intestine of the cockroach, *Stylopuga* (*Blatta*, *Periplaneta*) *orientalis*. Very small organism.

*Treponema parvum* Duboscq and Lebailluy (Arch. Zool. Expér. et Gén., 10, 1912, 331.) From the intestine of the blenny, *Blennius paro*.

*Treponema perexilis* Duboscq and Lebailluy (Duboscq and Lebailluy, Arch. Zool. Expér. et Gén., 10, 1912, 331; *Spirochaeta perexilis* Handle, Med. Res. Council Syst. of Bact., 8, 1931, 180.) From the blood of a marine fish, *Lepidogaster bimaculatus*.

*Treponema podocis* Ludovic and Blaisot (Compt. rend. Acad. Sci. Paris, 187,

Morphologically indistinguishable from *Leptospira icterohaemorrhagiae*.

Cultivation: Same as *Leptospira icterohaemorrhagiae*.

Immunology: Some cross-reaction with *Leptospira icterohaemorrhagiae*, but specific in higher dilutions of immune serum.

Source: From blood of dogs.

Habitat: A natural parasite of dogs. Causes a chronic disease of old dogs characterized by uremia, not jaundice. Fatal in 80 per cent of those infected. No intermediate host known. Probably transmitted by direct contact; possibly by healthy carriers.

Appendix: The species listed below are inadequately described and may be identical with those described in full.

*Leptospira aqueductum* (sic) Ford. (*Spirochaeta pseudoicterogenes aqueductum* Uhlenhuth and Zuelzer, Cent. f. Bakt., I Abt., Orig., 85, 1921, \*150; Ford, Textb. of Bact., 1927, 998) From fresh water of aqueducts. Probably a synonym of *Leptospira biflexa*.

*Leptospira asthenolysiae* Carbo-Noboa. (Bull. Inst. Past, 22, 1924, 898.) From blood, urine and organs of persons having dengue.

*Leptospira autumnalis* Topley and Wilson (Akiyami Type A, Koshina, Shiwozawa and Kitayama, Japan. Med. Wld., 4, 1921, 268; see also Jour. Exp. Med., 42, 1925, 873; Topley and Wilson, Princip. Bact. and Immun., 1st ed., 2, 1931, 1202; *Spirochaeta autumnalis* A, quoted from Hindle, Med. Res. Council Syst. of Bact., 8, 1931, 312; *Spirochaeta autumnalis* Hindle, *ibid.*) The cause of akiyami or harvest sickness in Japan. May be identical with *Leptospira icterohaemorrhagiae*.

*Leptospira bataviae*. (1925, quoted from Gispén and Schüffner, Cent. f. Bakt., I Abt., Orig., 144, 1939, 427.) From a case of fever in the Dutch East Indies. Probably a synonym of *Leptospira hebdomadis*.

*Leptospira biliohemoglobinuriae* (Blanchard and Lefrou) Noguchi (*Spirochaeta bilio-hemoglobinuriae* Blanchard

and Lefrou, Compt. rend. Acad. Sci., Paris, 175, 1922, 602; Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 190.) From cases of black-water fever.

*Leptospira bonariensis* Savino and Hennella. (Rev. Inst. Bact. "Dr. Carlos G. Malbram", 12, 1944, 182.) From gray rats.

*Leptospira botis* Noguchi. (New York State Med. Jour., 22, 1922, 426.) From the gastric mucosa of the ox.

*Leptospira couryi* Gomes de Faria. (Compt. rend. Soc. Biol., Paris, 90, 1924, 55; *Spirochaeta couryi* Hindle, Med. Res. Council Syst. of Bact., 8, 1931, 317.) From the blood of persons having dengue.

*Leptospira dentale* Perrin. (Rev. Mex. de Biol., 2, 1922, 171.) Found in the pus of bucco-maxillary gangrene.

*Leptospira grippo-typhosa* Topley and Wilson. (Topley and Wilson, Princip. Bact. and Immun., 2nd ed., 1936, 728; *Spirochaeta dmitrovi* Rimpau, Schlossberger and Kathe, Cent. f. Bakt., I Abt., Orig., 141, 1938, 320.) The cause of swamp fever in Europe. Probably synonymous with *Leptospira hebdomadis*. Also see Raschenin, Cent. f. Bakt., I Abt., Orig., 115, 1929, 438 and 450; Dinger and Verschaffelt, Ann. Inst. Past, 45, 1930, 396.

*Leptospira haemoglobinuriae* Schüffner. (Geneesk. Tijdschr. Ned. Indië, 58, 1918, 352; *Spirochaeta haemoglobinuriae* Hindle, Med. Res. Council Syst. of Bact., 8, 1931, 314.) From the blood of a Javanese patient suffering from an attack of black-water fever.

*Leptospira icterohemoglobinuriae* Schüffner. (Schüffner, Geneesk. Tijdschr. v. Ned. Indië, 58, 1918, 352, according to Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, *Spirochaeta icterohemoglobinuriae* Schüffner, Mededeel. Burgerl. Geneesk. Dienst in Nederl. Indië, 58, 1918, 7 (according to Blanchard and Lefrou, Compt. rend. Acad. Sci., Paris, 175, 1922, 602); *Trepomena icterohemoglobinuriae* Brumpt,

Brumpt, *ibid*, 508, *Leptospira icterogenes* Ford, Textb of Bact., 1927, 994; *Leptospira nodosa* Ford, *ibid.*, 993.) From Greek *icterus*, jaundice and *hemorrhagiae*, bleeding.

Morphology: 0.25 to 0.3 by 6 to 9 microns and occasionally 20 to 25 microns

Spiral amplitude. 0.4 to 0.5 micron, regular, rigid.

Spiral depth: 0.3 micron, regular.

Waves: One or more gentle waves throughout entire length. When in liquid media, one or both ends may be semicircularly hooked, while in semisolid media the organism appears serpentine, waved or bent. Very active flexibility.

Terminal filament and flagella absent.

Body stains reddish by Giemsa's stain

Bile salts (10 per cent): Easily dissolved

Saponin (10 per cent). Completely resistant

Cultured easily in medium containing 10 per cent rabbit serum, 0.2 per cent agar, slight amount of hemoglobin in salt or Ringer's solution. Does not grow in surface colonies

Temperature range: 25° to 37°C Remains alive longer at 25°C.

Pathogenic for guinea pigs and deer-mice

Habitat The cause of infectious jaundice in man (Weil's disease) Found in the kidneys, urine and blood of wild rats No insect vector known Found free living in water and slime (in mines)

2 *Leptospira hebdomadis* (Ido et al.) Noguchi (*Spirochaeta nanukayami* Ido, Hoki, Ito and Wani, Nippon Gakkaï Zasshi, 6, 1917, No. 5, *Spirochaeta hebdomadis* Ido, Ito and Wani, Jour Exp Med, 28, 1918, 433, *Spirochaudinna hebdomadis* Castellani and Chalmers, Man Trop Med, 3rd ed., 1919, 418, Noguchi, Jour Exp Med, 30, 1919, 17; *Treponema hebdomadis* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 501.) From Latin, seven days.

Morphologically indistinguishable from

*Leptospira icterohaemorrhagiae* but can be distinguished serologically.

In man causes less jaundice than *Leptospira icterohaemorrhagiae* and is never fatal.

Identical with Type B, *Leptospira autumnalis*.

Slightly pathogenic for young guinea pigs.

Is carried by the field vole (*Microtus montibelli*)

Habitat: Cause of seven-day fever or gikiyami in Japan

3 *Leptospira biflexa* (Wolbach and Binger) Noguchi. (*Spirochaeta biflexa* Wolbach and Binger, Jour. Med. Res., 30, 1914, 23; Noguchi, Jour Exp. Med., 27, 1918, 585; *Spirochaeta pseudo-icterogenes (aquatilis)* Uhlenhuth and Zuelzer, Cent. f. Bakt., I Abt., Orig., 85, 1921, \* 141; *Spirochaeta pseudoicterogenes* Uhlenhuth and Zuelzer, Klin. Wochenschr., 1, 1922, 2121; *Spirochaeta pseudo-icterohaemorrhagiae* Vincent, Compt. rend. Soc. Biol., Paris, 95, 1926, 1472; *Leptospira pseudoicterogenes* Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461.) From Latin, doubly bent.

Size: 0.2 to 0.25 by 5 to 7 microns with tapering ends Spiral amplitude 0.2 to 0.25 micron. Will pass through an L5 candle filter.

Waves 22 to 30 in number.

Stains: Best results with Giemsa's stain

Culture Can grow in distilled water plus 0.1 per cent potassium nitrate. Rabbit serum in distilled water is best medium

Optimum temperature 20°C.

Antigenically distinct from *Leptospira icterohaemorrhagiae*.

Not pathogenic

Source From tap water, ponds and pools in Berlin

Habitat Fresh water.

4 *Leptospira canicola* Okell et al. (Okell, Dalling and Pugh, Vet. Jour., 81, 1925, 3) From Latin, dog-dweller.

Nouveau Traité de Médecine, Paris, 4, 1922, 501 ) From the blood in a case of blackwater fever.

*Leptospira interrogans* (Stimson) Noguchi (*Spirochaeta interrogans* Stimson, U S Public Health Rept., Part I, 22, 1907, 541, *Leptospira icteroides* Noguchi, Jour Exp Med., 29, 1919, 581; *Treponema interrogans* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 503, *Treponema icteroides* Brumpt, *ibid*; *Spirochaeta icteroides* Lehmann and Neumann, Bakt. Dng., 7 Aufl., 2, 1927, 576, Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 454 ) Noguchi (1928) regards this species as identical with *Leptospira icterohaemorrhagiae*.

*Leptospira pettiti* (Fiessinger) Hindle (*Spirochaete pettiti* Fiessinger, Ann. de Méd., 5, 1918, 156, *Treponema pettiti* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 510, Hindle, Med. Res. Council Syst. of Bact., 8, 1931, 316, *Spirochaeta pettiti* Hindle, *idem*, not *Spirochaeta pettiti* Row, Jour. Trop. Med. and Hyg., 1922, 361.) From urine. Morphologically indistinguishable from *Leptospira icterohaemorrhagiae*.

*Leptospira pyrogenes* Vervoort. (Vervoort, Geneesk. Tijdschr. v. Ned. Indië, 63, 1923, 800, *Spirochaeta febrilis* Vervoort, Rep. Far East Assoc. Trop. Med., London, 1923, 683; *Spirochaeta pyrogenes* Hindle, Med. Res. Council Syst. of Bact., 8, 1931, 314 ) From the blood of persons suffering from dengue like fevers in Sumatra. Pathogenic.

*Leptospira sazkobing* Petersen (Acta Path. et Microbiol. Scand., 21, 1911, 165 ) A new serological type.

*Leptospira salina* Ford (*Spirochaeta pseudointerrogans salina* Uhlenhuth and

Zuelzer, Cent. f. Bakt., I Abt., Orig., 85, 1921, \*150, Ford, Textb. of Bact., 1927, 998 ) From salt water.

*Leptospira trimerodonta* (Hoffmann) Noguchi (*Spirochaeta trimerodonta* Hoffmann, Deutsch. med. Wochenschr., 46, 1920, 257, *Leptospira dentium* Hoffmann, *ibid*, 625; *Leptospira buccalis* Fontana, according to Pettit, Contribution à l'Étude des Spirochétidés, Vanves, II, 1928, 232; Noguchi, in Jordan and Falk, Newer Knowledge Bact. and Immun., 1928, 461 ) From the oral cavity. May be synonymous with *Leptospira icterohaemorrhagiae*.

*Spirochaeta anthropopitheci* Wilbert and Delorme (Ann. Inst. Past., 41, 1927, 1147.) Pathogenic for chimpanzees in French Guinea. Probably identical with *Leptospira icterohaemorrhagiae*.

*Spirochaeta elusa* Wolbach and Binger (Wolbach and Binger, Jour. Med. Res., 50, 1914, 9, *Treponema elusum* Bergey et al., Manual, 1st ed., 1923, 428 ) From pond water. Not pathogenic. For a description of this species, see Bergey et al., Manual, 5th ed., 1939, 957.

*Spirochaeta ictero-uraemia canis* Klarckenbeck (Tijdschr. Diergeneesk., 55, 1928, 227 ) From the kidneys of dogs. Pathogenic for guinea pigs. May be synonymous with *Leptospira icterohaemorrhagiae* or *L. canicola*.

*Spirochaeta pseudohebdomadis* Zuelzer. (1923, in Prowazek, Handb. d. path. Protoz., 3, 1931, 1671 ) Probably identical with *Leptospira hebdomadis*.

*Spirochaeta trimeres* Hoffmann. (Deutsch. med. Wochenschr., 46, 1920, 257.) From the oral cavity. May be synonymous with *Leptospira trimerodonta*.

## III. Plant pathogens, causing leaf spot, leaf stripe and similar diseases.

## 1. Green fluorescent pigment produced.

## a. Gelatin liquefied.

## b. Acid from sucrose.

## c. Nitrites produced from nitrates.

65. *Pseudomonas martyniae*.66. *Pseudomonas striafaciens*.67. *Pseudomonas tomato*.

## cc. Nitrites not produced from nitrates.

## d. Growth in 5 per cent salt.

68. *Pseudomonas aceris*.69. *Pseudomonas angulata*.70. *Pseudomonas aptata*.71. *Pseudomonas primulae*.72. *Pseudomonas viridilivida*.

## dd. No growth in 5 per cent salt

## e. Beef peptone agar turns brown.

73. *Pseudomonas delphinii*.

## ee. Beef peptone agar uncolored.

74. *Pseudomonas berberidis*.75. *Pseudomonas coronafaciens*.75a. *Pseudomonas coronafaciens* var. *atropurpurea*.76. *Pseudomonas lachrymans*.77. *Pseudomonas maculicola*.78. *Pseudomonas marginata*.79. *Pseudomonas medicaginis*.79a. *Pseudomonas phaseolicola*.80. *Pseudomonas pisi*.81. *Pseudomonas syringae*.

## ddd. Growth in salt solutions not recorded.

82. *Pseudomonas atrofaciens*.83. *Pseudomonas cumini*.84. *Pseudomonas desaiana*.85. *Pseudomonas erodii*.86. *Pseudomonas apii*.87. *Pseudomonas matthiolae*.88. *Pseudomonas mors-prunorum*.89. *Pseudomonas rimaefaciens*.90. *Pseudomonas papulans*.91. *Pseudomonas pseudozoogloeae*.92. *Pseudomonas tabaci*.

## eee Nitrite production not reported.

93. *Pseudomonas lapsa*.

## bb. No acid from sucrose.

## c. Nitrites produced from nitrates.

94. *Pseudomonas bowlesiae*.95. *Pseudomonas intybi*.96. *Pseudomonas marginalis*.97. *Pseudomonas setariae*.

SUPPLEMENT NO. 1.

ORDER RICKETTSIALES

April, 1947.

## ORDER RICKETTSIALES GIESZCZYKIEWICZ.

(Bull. Intern. Acad. Polon. Sci., Classe Math. Nat., B(1), 1939, 9-30.)

Small, rod-shaped, coccoid, spherical and irregularly-shaped microorganisms which stain lightly with aniline dyes. Gram-negative. Usually not filterable. Cultivated outside the body, if at all, only in living tissue, embryonated eggs or rarely in media containing body fluids. Parasitic organisms intimately associated with tissue cells and erythrocytes, chiefly in vertebrates and often in arthropods which act as vectors. The intracellular parasites of *Protozoa* may also belong here. May cause diseases in man or animals, or both.

*Key to the families of order Rickettsiales.*

- I. Intracellular parasites, or parasites intimately associated with tissue cells. Do not occur in erythrocytes. Frequently cause diseases of vertebrates transmitted by arthropod vectors.  
Family I *Rickettsiaceae*, p. 1083.
- II. Facultative intracellular or extracellular parasites found characteristically in or on the erythrocytes of vertebrates. May be transmitted by arthropod vectors.  
Family II *Bartonellaceae*, p. 1100.
- III. Intracellular parasites found in vertebrate tissues and not transmitted by arthropod vectors.  
Family III *Chlamydozoaceae*, p. 1114.

## \*FAMILY I RICKETTSIACEAE PINKERTON.

(Pinkerton, *Parasitology*, 28, 1936, 186, *Rickettsiales* Buchanan and Buchanan, *Bacteriology*, 4th ed., New York, 1938, 49.)

Small, often pleomorphic, rod-shaped, ovoid, coccoid and coccus-shaped bacterium-like organisms, intimately associated with arthropod tissues, usually in an intracellular position. Stain lightly with aniline dyes. Gram-negative. Have not been cultivated to date in cell-free media. May be parasitic to man and other animals causing diseases (typhus and related ills) that are transmitted by arthropod vectors (lice, fleas, ticks, mites and probably other ectoparasites).

*Key to the genera of family Rickettsiaceae.†*

- I. Cells rod-shaped, ellipsoidal and coccoid.
  - A. Non-filterable.  
Genus I *Rickettsia*, p. 1084.
  - B. Filterable.  
Genus II *Coxiella*, p. 1092.
- II. Cells spherical, occasionally elongated.  
Genus III. *Cowdria*, p. 1094.

\* Prepared by Dr. Ida A. Bengtson (retired), National Institute of Health, Bethesda, Maryland, November, 1946. Through the courtesy of Dr. Edward A. Steinhaus much use was made of material from his book, *Insect Microbiology*, Ithaca, 1946, 763 pp. before it was generally available.

† Includes only those rickettsiae which have been rather completely studied. For additional rickettsiae, see appendix.

Genus I. *Rickettsia* da Rocha-Lima.

(Berl. klin. Wchnschr., 53, 1916, 567-569.) Named for Howard Taylor Ricketts who lost his life studying typhus fever.

Small, often pleomorphic, rod-shaped to coccoid organisms occurring intracytoplasmically in lice, fleas, ticks and mites, or sometimes intranuclearly. Stain lightly with aniline dyes. Gram-negative. Non-filterable. Have not been cultivated in cell-free media. Parasites of man and animals which are the etiological agents of epidemic typhus, murine or endemic typhus, Rocky Mountain spotted fever, tsutsugamushi disease, rickettsialpox and other diseases.

For reasons that are discussed elsewhere (Bengtson, Jour. Bact., 53, 1947, 325) the genus *Dermacentrozoon* has been united with the genus *Rickettsia*.

The type species is *Rickettsia prowazekii* da Rocha-Lima.\*

Key to the species of genus *Rickettsia*.

- |                  |                                      |

1. *Rickettsia prowazekii* da Rocha-Lima. (da Rocha-Lima, Berl. klin. Wchnschr., 53, 1916, 567; *Rickettsia exanthematophyl* Kodama, Kitasato Arch. Exper. Med., 9, 1932, 360, *Rickettsia prowazeki* var. *prowazeki* Pinkerton, Parasitology, 28, 1936, 186; *Rickettsia prowazeki* sub-species *prowazeki* Philip, Amer. Jour. Hyg., 57, 1943, 307.) Named for S. von Prowazek who lost his life studying typhus fever.

Minute coccoid, ellipsoidal and ovoid forms to short rods, sometimes long rods and occasionally filamentous forms, often in pairs and occasionally in chains. In infected lice the minute coccoid and

paired coccoid forms predominate over the short and long rods and the filamentous forms which are up to 40 microns in length. Single elements 0.25 by 0.4 to 0.3 by 0.45 micron. Pairs range from 0.25 by 0.7 to 0.3 by 1.1 microns. In yolk sacs the organisms vary in size from minute coccoid forms in heavily infected tissue to rod forms resembling small bacteria in lightly infected tissue. Within the same smear of infected mammalian cells and in chick embryo tissue the organisms are quite uniform in size and morphology. Occur intracytoplasmically in vascular endothelial cells and in serosal cells. Non-motile.

\* The Editors of the MANUAL follow Recommendation XL of the International Botanical Code (see p. 59) in regard to the endings used for specific names. This calls for the use of the *ii* ending for epithets taken from the name of a man ending in a low name. Some students of the *Rickettsiaceae* follow the modern patronymics based on all other names of man.

The organisms are colored purplish with the Giemsa stain, the two individuals of a pair being connected by a zone of faintly blue stained material. They are colored blue with Castafieda stain (Jour. Inf. Dis., 47, 1930, 416) and bright red against a blue background with Machiavello stain (Rev. Chilena de Hig. y Med. Prev., 1, 1937, 101). Gram-negative.

**Cultivation.** In plasma tissue cultures of mammalian cells, in the louse intestine, in modified Maitland media with and without agar, on chorio-allantoic membrane and yolk sac of chick embryo, the latter being currently the medium of choice.

**Optimum temperature** 32°C in plasma tissue culture, 35°C in chick embryo cells.

**Immunology:** Immunity prolonged but may not be complete in man. Indistinguishable from endemic (murine) typhus in cross immunity tests in guinea pigs, but distinguishable from Rocky Mountain spotted fever and other rickettsial diseases in such tests. Neutralizing antibodies are found in the serum of recovered guinea pigs and convalescent humans up to 2 to 3 weeks after deferescence. Killed vaccines produced from infected lice and from infected yolk sacs afford a high degree of protection against the disease. Hyperimmune antisera for therapeutic use have been produced in rabbits by injection with infected yolk sac suspensions and in horses and donkeys with infected mouse lung suspensions.

**Serology:** Strains from various parts of the world are closely related as determined by complement fixation, are

distinguishable from other rickettsiae by agglutination, complement fixation and precipitin tests; have a common antigenic factor (alkali stable polysaccharide) with *Proteus* OX19; and have a soluble antigen in yolk culture.

**Lethal effect.** Heavily infected yolk sac cultures injected intravenously or intraperitoneally are fatal to white mice in a few hours.

**Resistance to chemical and physical agents.** Readily inactivated by heat and chemical agents. A temperature of 50°C kills the organism in 15 to 30 minutes, and 0.5 per cent phenol and 0.1 per cent formalin kill the organism.

**Pathogenicity:** Pathogenic for man, apes, monkeys, guinea pigs, cotton rats, gerbilles, the louse (*Pediculus humanus*). Inapparent infections occur in white mice, white rats and rabbits. A characteristic febrile reaction with no mortality and without testicular swelling occurs in the guinea pig. Passage in guinea pigs is accomplished by transfer of blood or brain from infected animals. Causes a febrile disease with exanthema and high mortality in man.

**Source.** Seen in the blood of typhus patients and in smears of epithelial cells of the intestinal tract of lice fed on typhus patients.

**Habitat.** The body louse (*Pediculus humanus* var. *corporis*), head louse (*Pediculus humanus* var. *capitis*) and *Pediculus longiceps*. The etiological agent of epidemic typhus (European typhus, classical typhus, typhus exanthematicus).

2 \**Rickettsia typhi* (Wollach and Todd) Philip. (*Dermacentrozeus*

\* Some may regard the binomial *Rickettsia typhi* as invalid because of its previous use by de Amaral and Monteiro for the organism causing eastern Rocky Mountain spotted fever. However, because the binomial *Dermacentrozeus typhi* Wollach and Todd clearly has priority and because the binomial proposed by de Amaral and Monteiro has never come into general use, *Rickettsia typhi* Philip has been accepted for use in the West. If Philip's binomial had been rejected, then it would have been necessary to accept *Rickettsia manchuriae* Kodama et al. as this appears to have priority over the more generally used *Rickettsia mooseri* Monteiro.—Editors.

*typhi* Wolbach and Todd (not Tood), Ann. Inst. Past., 54, 1920, 158; minute intracellular bodies, Mooser, Jour. Inf. Dis., 43, 1928, 261; *Rickettsia manchuriae* Kodama, Takahashi and Kono, Saikingaku-Zasshi (Jap.), No. 426, 427, Aug. and Sept., 1931; see Kodama, Kono and Takahashi bibliography, Kitasato Arch. Exper. Med., 9, 1932, 95; *Rickettsia mooseri* Monteiro, Mem. Inst. Butantan, 6, 1931, 97 (pub July, 1932), see de Amaral and Monteiro, bibliography, *ibid.*, 7, 1932, 267; *Rickettsia exanthematosebri* Kodama, Kitasato Arch. Exp. Med., 9, 1932, 360; *Rickettsia muricola* Monteiro and Fonseca, Brazil Med., 46, 1932, 1032; *Rickettsia murina* and *Rickettsia Fletcheri* Megaw, Trans. Roy. Soc. Trop. Med. Hyg., 29, 1935, 105; *Rickettsia prowazeki* var. *mooseri* Pinkerton, Parasitology, 28, 1936, 185; *Rickettsia prowazeki* sub-species *typhi* Philip, Amer. Jour. Hyg., 57, 1943, 304; *Rickettsia typhi* Philip, *idem*; not *Rickettsia typhi* de Amaral and Monteiro, Rev. Sud. Amér. de Méd. et Chirurg., 4, 1933, 806.) From *M. L. typhus*, typhus.

Resembles *Rickettsia prowazeki* in morphological and staining properties. Non-motile. Gram-negative.

Cultivation May be cultivated in plasma tissue culture of mammalian cells, in modified Maitland media with and without agar, in fleas, in the peritoneal cavity of X-rayed rats, in the lungs of white mice and in white rats following intranasal inoculation, in the lungs of rabbits following intratracheal inoculation, in the chorio-allantoic membrane and the yolk sac of the chick embryo.

Optimum temperature 35°C in chick embryo cells.

Immunology: Prolonged immunity in man and animals following infection. Complete cross immunity between epidemic and endemic typhus in guinea pigs recovered from infections with *Rickettsia prowazeki* and *Rickettsia typhi*. No cross immunity between en-

demic typhus and Rocky Mountain spotted fever, Q fever or tsutsugamushi disease in guinea pigs.

Serology: Distinguishable from the rickettsiae of spotted fever, Q fever and tsutsugamushi disease by complement fixation, agglutination and precipitin tests, less readily from *R. prowazeki* by these tests. Has common antigenic factor with *Proteus* OX19, and soluble antigen in yolk-sac cultures.

Lethal effect: Heavily infected yolk sac cultures injected intravenously or intraperitoneally fatal to white mice in a few hours.

Pathogenicity: Pathogenic for man, apes, monkeys, rabbits, guinea pigs, white rats, eastern cotton rat, white mice, gerbils. Other susceptible animals include the woodchuck, house mouse, meadow mouse, white-footed mouse, old-field mouse, cotton mouse, golden mouse, wild rat (*Rattus norvegicus*), wood rat, rice rat, flying squirrel, gray squirrel, fox squirrel, gophers, cotton-tail rabbit, swamp rabbit, chipmunk, skunk, opossum and cat. A characteristic febrile reaction occurs in the guinea pig with testicular swelling without ulceration, after intraperitoneal inoculation. Passage in guinea pigs is accomplished by transfer of testicular washings or blood from infected animals. Cause of a febrile disease with exanthema in man, with low mortality.

Source: Seen by Wolbach and Todd (*loc. cit.*) in the endothelial cells of the capillaries, arterioles and veins in sections of skin from cases of Mexican typhus (tabardillo). Also described by Mooser (*loc. cit.*) in sections and smears of the proliferated tunica vaginalis of guinea pigs reacting to the virus of Mexican typhus.

Habitat: Infected rat fleas (*Xenopsylla cheopis*, *Xenopsylla astia*), infected chicken fleas (*Echidnophaga gallinacea*) found on wild rats, and the rat louse (*Polyplax spinulosus*). Wild rats and field mice act as the reservoir of infection. The etiological agent of en-

demic (murine) typhus which is transmitted to man by the rat flea.

3. *Rickettsia rickettsii* (Wolbach) Brumpt. (*Dermacentrozetes rickettsii* Wolbach, Jour. Med. Res., 41, 1919-20, 87; *Rickettsia rickettsii* Brumpt, Précis de Parasitologie, 3rd ed., 1922, 757, *Rickettsia brasiliensis* Monteiro, Mem. Inst. Butantan, 6, 1931, 3; \**Rickettsia typhi* de Amaral and Monteiro, Rev. Sud-Amér. de Méd. et Chirurg., 4, 1933, 806, *Dermacentrozetes rickettsii* var. *brasiliensis* Pinkerton, Parasitology, 28, 1936, 186.) *Rickettsia dermacentrozetis*, a corruption of *Dermacentrozetes rickettsii*, though widely used, has no genuine taxonomic standing. Named for Howard Taylor Ricketts, who first transmitted the disease from human cases to monkeys and guinea pigs with the production of characteristic symptoms and lesions and fatal effect.

Minute paired organisms surrounded by a narrow clear zone or halo and often lanceolate, resembling in appearance a minute pair of pneumococci. Approximately 0.2 to 0.3 micron by 1 micron. Non-motile.

In smears of mammalian tissues there occur in addition to the lanceolate forms, slender rod-shaped forms stained blue with the Giemsa stain, sometimes exhibiting polar granules, stained purplish or reddish. There are also minute pale blue-staining rounded forms. In the tick there are three forms: (1) Pale blue bacillary forms curved and club-shaped, (2) smaller bluish rods with deeply staining chromatoid granules and (3) more deeply staining, purplish, lanceolate forms. A very minute form may appear in tightly packed masses in the nuclei of the cells. Occurs in the cytoplasm and nucleus in all types of tissue in the tick and in the vascular endothelium, in the serosal cells of the peritoneal

cavity, in the smooth muscle cells of arteriolar walls and in the macrophages of mammals.

In yolk sac cultures and in the Maitland media cultures, bacillary forms often occur in pairs. In single smears from infected yolk sacs, the rickettsiae are rather uniform in size and morphology and are definitely larger than *Rickettsia prowazekii* and *Rickettsia typhi*. They also grow more sparsely. Stain blue with the Castañeda stain and bright red against a blue background of tissue with the Machiavello stain.

Cultivation. May be cultivated in plasma tissue culture of mammalian cells, in Maitland media with and without agar, on the chorio-allantoic membrane and in the yolk sac of the chick embryo, and in ticks.

Optimum temperature 32°C in plasma tissue culture, 35°C in chick embryo cells.

Immunology. Prolonged immunity in man and animals after recovery from infection. Killed vaccines produced from infected ticks and from infected yolk sacs afford considerable protection against the disease. Therapeutic antisera have been produced by the injection of rabbits with tick virus and with infected yolk sac. No cross immunity between spotted fever in guinea pigs recovered from infections with *Rickettsia rickettsii* and typhus in guinea pigs recovered from infections with *Rickettsia prowazekii* and *Rickettsia typhi*. Cross immunity between spotted fever in guinea pigs recovered from infections with *Rickettsia rickettsii* and boutonneuse fever in guinea pigs recovered from infections with *Rickettsia conorii*, but spotted fever vaccine does not protect against boutonneuse fever of the Mediterranean area or against infections with the South African strains of *Rickettsia conorii*.

\* Erroneously applied by de Amaral and Monteiro to the so-called eastern type of Rocky Mountain spotted fever.—Editors.

**Serology** Distinguishable from *Rickettsia prowazekii* and *Rickettsia typhi* by complement fixation and agglutination with specific antigens. Distinguishable from *Rickettsia conorii* by complement fixation, though some degree of cross fixation indicates antigenic relationship. Has common antigenic factor with *Proteus* OX19 but not distinguishable from *Rickettsia prowazekii* and *Rickettsia typhi* by Weil-Felix test.

**Resistance to chemical and physical agents:** Readily inactivated by heat and chemical agents. Destroyed by a temperature of 50°C in 10 minutes, and by 0.5 per cent phenol and 0.1 per cent formalin. Destroyed by desiccation in about 10 hours.

**Pathogenicity:** Pathogenic for man, monkeys and guinea pigs. Rabbits and white rats are moderately susceptible. Animals susceptible in varying degrees include species of ground squirrels, tree squirrels, chipmunks, cotton-tail rabbits, jack rabbits, snowshoe rabbits, marmots, wood rats, weasels, meadow mice and deer mice. In Brazil the opossum, rabbit, dog and cavy have been found naturally infected and the Brazilian plains dog, capybara, coati and certain bats are also susceptible. Sheep are mildly susceptible.

A febrile reaction occurs in guinea pigs with typical scrotal lesions, involving petechial hemorrhages in the skin, which may become necrotic. Virulent strains kill 80 to 90 per cent of the animals, milder strains kill 20 to 25 per cent. Passage in guinea pigs is accomplished by transfer of blood from infected animals. A febrile reaction accompanied by exanthema occurs in man. Mortality is high in some localities, low in others.

**Source** Seen by Ricketts (*Jour. Amer. Med. Assoc.*, 52, 1909, 379) in the blood of guinea pigs and monkeys experimentally infected with Rocky Mountain spotted fever and in the salivary glands, alimentary sac and ovaries of infected

female *Dermacentor* ticks and in their ova.

**Habitat:** Infected wood tick (*Dermacentor andersoni*) and the dog tick (*Dermacentor variabilis*), also the rabbit tick (*Haemaphysalis leporis-palustris*), *Amblyomma brasiliensis*, *Amblyomma cajennense*, *Amblyomma striatum*, *Amblyomma americanum* and *Ixodes dentatus*. A number of ticks belonging to the genera *Amblyomma*, *Dermacentor*, *Rhipicephalus*, *Ornithodoros* and *Haemaphysalis* have been experimentally infected. The virus is transmissible through the ova of female ticks. The etiological agent of Rocky Mountain spotted fever, São Paulo exanthematic typhus of Brazil, Tobia fever of Colombia and spotted fever of Minas Geraes which are all transmitted to man by the bite of infected ticks.

4. *Rickettsia conorii* Brumpt.  
(Brumpt, *Compt. rend. Soc. Biol.*, Paris, 110, 1932, 1199; *Rickettsia megawii* var. *pijperi* do Amaral and Monteiro, *Mem. Inst. Butantan*, 7, 1932, 361; *Rickettsia blanc*, Caminopétros, 1<sup>st</sup> Cong. Internat. Hyg. Mediterr., Rapports et *Compt. rend.*, 2, 1932, 202; *Dermacentrozeus rickettsi* var. *pijperi* Mason and Alexander, *Onderst. Jour. Vet. Sci. and An. Indust.*, 15, 1939, 74; *Dermacentrozeus rickettsi* var. *conorii* Mason and Alexander, *ibid*; *Dermacentrozeus conorii* Steinhilber, *Insect Microbiology*, 1946, 339.) Named for A. Conor who with A. Bruch published in 1910 the first clinical description of boutonneuse fever.

Resembles *Rickettsia rickettsii*. In the tick, diplococcoid and diplobacillary forms predominate, though when the rickettsiae occur in compact masses they are smaller and more coccoid. In tissue cultures the organisms are lanceolate, diplococcoid, and diplobacillary, occurring in the nuclei as well as in the cytoplasm of the cells. Size 0.3 to 0.4 by 1 to 1.75 microns. Non-motile.

Stain purplish with the Giemsa stain,

blue with the Castaldi's stain and bright red with a blue background with the Machiavello stain. Gram-negative.

Cultivation: May be cultivated in plasma tissue culture of mammalian cells, in modified Maitland media, and in the yolk sacs of chick embryos.

Immunology: The disease is related immunologically to Rocky Mountain spotted fever with which it cross immunizes, but the spotted fever vaccine does not protect against the Mediterranean and South African strains of bouton-neuse fever.

Serology: Distinguishable from *Rickettsia rickettsii* by complement fixation. Has a common antigenic factor with *Proteus* OX19 and OX2.

Pathogenicity: Pathogenic for man and guinea pigs. It is also pathogenic in varying degrees for dogs, horses, spermophiles, monkeys, rabbits, gerbilles and white mice.

Bouton-neuse fever is a much less virulent infection for the guinea pig than Rocky Mountain spotted fever. A temperature reaction occurs, accompanied by serotal swelling but there is no sloughing. There is practically no mortality. Passage in guinea pigs is accomplished

by transfer of blood from an infected animal.

In man, localized primary sores (taches noires) and an inflammatory reaction in the regional lymph nodes occur at the site of the tick bite. A febrile reaction with exanthema occurs and mortality is low.

Source: Seen by Camunopetros (Compt. rend. Soc. Biol., Paris, 110, 1932, 311) in smears from the tunica vaginalis of guinea pigs inoculated with infected dog ticks (*Rhipicephalus sanguineus*).

Habitat: The brown dog tick (*Rhipicephalus sanguineus*) and also the ticks, *Amblyomma hebraeum*, *Haemaphysalis leachi*, *Rhipicephalus appendiculatus* and *Bosophilus decoloratus*. Transmissible through the ova of adult female ticks. The probable animal reservoir is the dog. The etiological agent of bouton-neuse fever in man, also known as eruptive, Mediterranean or Marseilles fever and probably Kenya typhus and South African tick bite fever, though the identity of the latter with bouton-neuse fever has been questioned.

5 *Rickettsia tsutsugamushi* (Hayashi) Ogata (*Theileria tsutsugamushi*)

\* Some may question the use of this binomial on the ground that Hayashi thought that this species was possibly or probably protozoan in nature when he proposed the name *Theileria tsutsugamushi* (loc. cit.) in 1920. However he questions whether *Theileria* is the correct generic name in this paper and accepts the viewpoint that this organism is a rickettsia in a paper published in 1921 entitled, On Rickettsia, Trans. Jap. Path. Soc., 14, 1921, 198-201. He does not use the binomial *Rickettsia tsutsugamushi* in this paper as indicated by some of his friends in latter papers (Ogata, loc. cit., Kawamura, loc. cit.) and apparently first uses it himself in a paper entitled, On Tsutsugamushi Disease, Jap. Path. Soc., 22, 1932, 693.

Hayashi was not the first to recognize the probable rickettsial nature of the organism of the tsutsugamushi disease (see Blake et al., Amer. Jour. Hyg., 41, 1915, 257-262) and some even question whether any of the bodies that he found in human lymphocytes from lymph nodes, in mononuclear endothelial phagocytes of the spleen and lymph nodes, and in tissues taken from the region of the mite bite in patients suffering from tsutsugamushi fever were the same as organisms described as *Rickettsia orientalis* by Nagayo et al. (loc. cit.).

This position is not supported, however, by Nagayo and his associates who admit that their organisms are identical with some of the organisms described by Hayashi. Mitamura (Trans. Jap. Path. Soc., 21, 1931, 463) sums this up as follows: "Wir stellen

Hayashi, Jour. Parasit., 7, 1920, 63; \**Rickettsia orientalis* Nagayo, Tamiya, Mitamura and Sato, Jikken Igaku Zasshi, 14, May 20, 1930, 8 pp.; †*Rickettsia tsutsugamushi* Ogata, Cent. f. Bakt., I Abt., 122, 1931, 249; *Rickettsia akamushi* Kawamura and Inagawa, *ibid.*, 122, 1931, 258, *Rickettsia orientalis* var. *schauffneri* de Amaral and Monteiro, Mem. Inst. Butantan, 7, 1932, 360; *Rickettsia megawi* de Amaral and Monteiro, *idem*; *Rickettsia megawi* var. *etcheri* de Amaral and Monteiro, *ibid.*, 361, *Rickettsia tsutsugamushi-orientalis* Kawamura, Nishin Igaku, 23, 1934, 000; *Rickettsia pseudotypi* Vervoort, see Donatien and Lestoquard, Acta Conv. Tertii Trop. atque malariae morbis, pars I, 1933, 564; *Rickettsia sumatranus* (sic) Kouwenaar and Wolff, Proc. 6th Pacific Sci. Cong. (1939), 5, 1942, 636; *Dermacen-*

*trorenus orientalis* Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in modern biology), 19, 1945, 13) From two Japanese ideographs transliterated *tsutsuga*, something small and dangerous, and *mushi*, a creature now known to be a mite. If the *i* ending is accepted as forming a Latin genitive the modern meaning of the species name *tsutsugamushi*, would be 'of a dangerous mite'.

Small pleomorphic bacterium-like microorganisms, usually thicker than *Rickettsia prowazekii*, *Rickettsia typhi*, *Rickettsia rickettsii* and *Coxiella burnetii* and less sharply defined. Ellipsoidal or rod-shaped, often appearing as a diplococcus or as a short bacillus with bipolar staining resembling the plague bacillus. Diffusely distributed in the cytoplasm of the cell. Size 0.3 to 0.5 by 0.8 to 2

nicht in Abrede dass Herr Hayashi bei einem kleinen Teil der von ihm beschriebenen Körperchen unsere *Rickettsia orientalis* vor sich gehabt hat". Hayashi vigorously defends his own observations in the same discussion and the following year after making comparative studies of strains of *Rickettsia orientalis* and his own *Rickettsia tsutsugamushi* reaches the following conclusion (*loc. cit.*) "*Rickettsia tsutsugamushi* and *Rickettsia orientalis* refer to one and the same species of microorganisms and there seems to be no way in which one can be recognized as differing from the other." Under these conditions the only valid name appears to be *Rickettsia tsutsugamushi*.—Editors.

\* These authors publish practically the same preliminary paper in three other places as follows: Compt. rend. Soc. Biol., Paris, 104, June 14, 1930, 637-641; Jap. Jour. Exper. Med., 8, Aug. 20, 1930, 309-318 and Trans. Jap. Path. Soc., 20, 1930, 556-566. The complete report on this work did not appear until the following year: Jap. Jour. Exper. Med., 9, March 20, 1931, 87-150.—Editors.

† This binomial apparently first appears in the literature in a review article by Kawamura (Handbuch der path. Microorganismen, Kollé and Wassermann, 3 Aufl., 8, 1930, 1398) where it is used incidentally and is attributed to Hayashi, 1923. The fact that Hayashi did not use *Rickettsia tsutsugamushi* before 1931 is confirmed by Mitamura (Trans. Jap. Path. Soc., 21, 1931, 463) who states in a footnote: "Kawamura und Ogata geben an, dass Hayashi 1923 für den Erreger den Namen *Rickettsia tsutsugamushi* vorgeschlagen hat. Eine solche Angabe Hayashi, ist nicht nur uns, sondern auch dem Autor, wie er uns persönlich erzählt, unbekannt." Ogata apparently first used *Rickettsia tsutsugamushi* in the title of a paper that he presented in 1930 to the 8th Cong. Far East Assoc. Trop. Med. which, however, appeared in the Transactions of the Congress, 2, June, 1932, 167-171. Meanwhile, the same paper with an added discussion of the nomenclature appeared in the Cent. f. Bakt., I Abt., Orig., 122, Oct. 1, 1931, 249-253 and it is this paper that is usually regarded as establishing the use of *Rickettsia tsutsugamushi* for this species.—Editors.

genus *Rickettsoides* da Rocha-Lima (*loc. cit.*).

6. *Rickettsia akari* Huebner, Jellison and Pomerantz. (Pub. Health Rept., 61, 1946, 1682.) From *Acarus*, a genus of mites.

Minute diplobacilli, occurring intracellularly and extracellularly, and bipolarly stained rods. Resemble typical rickettsiae morphologically. Non-motile.

Stain well by Machiavello's method, the organisms appearing bright red against a blue background. Stain poorly with methylene blue. Gram-negative. Occur intracytoplasmically and have been seen intranuclearly in yolk sac cells.

Cultivation: In the yolk sac of the chick embryo. No growth on artificial culture media.

Immunology. Guinea pigs recovered from rickettsialpox are immune to infection with strains isolated from infected mites.

Serology. Antigens prepared from infected yolk sacs are highly specific except for cross reactions with Rocky Mountain spotted fever antigens. Sera from convalescent patients fixed complement with the homologous antigen and usually with Rocky Mountain spotted fever antigens.

though at a lower titer. Does not have a common antigenic factor with *Proteus* strains except that low titers were obtained in a few recovered cases in agglutination tests with *Proteus* OX19.

Pathogenicity: Pathogenic for man with focal initial erythematous lesion and adenopathy, followed by fever and appearance of macular rash. No mortality. Experimental infections have been produced in white mice and guinea pigs by the inoculation of infected blood (irregularly), and of infected liver and spleen suspensions, infected brain, infected lymph nodes, tunica washings of infected animals and by infected yolk sacs. Symptoms in mice include inactivity, accelerated respiration, ruffled fur, with occasional deaths; in guinea pigs, fever and marked scrotal reactions. Infected embryos are killed in 4 to 7 days. It has not been found pathogenic for monkeys, distinguishing it from *Rickettsia conorii*. It is also probably more pathogenic for white mice than *Rickettsia conorii*.

Source. Blood of a human case of rickettsialpox in New York City.

Habitat: Blood of human cases and an ectoparasite of rodents, the mite (*Allo-dermanyssus sanguineus* Hirst). The etiological agent of human rickettsialpox.

## Genus II. *Coxiella* Philip.

(Subgenus *Coxiella* Philip, Amer. Jour. Hyg., 37, 1943, 306, *Coxiella* Philip, Pub. Health Repts., U S P. H S., 63, Jan. 9, 1948, 58, not Bengtson, *gen. nov.* as stated in first printing Manual, 6th ed., Jan. 26, 1948, 1092)

Small, pleomorphic, rod-shaped and coccoid organisms, occurring intracellularly in the cytoplasm and extracellularly in infected ticks. Stain lightly with aniline dyes. Gram-negative. They are filterable. Have not been cultivated in cell-free media. Parasites of man and animals which include the etiologic agent of Q fever.

The type species is *Coxiella burnetii* (Derrick) Bengtson

1 *Coxiella burnetii* (Derrick) Bengtson *comb. nov.* (*Rickettsia burnetii* Derrick, Med. Jour. Australia, 1, 1939, 14; *Rickettsia diapora* Cox, Pub. Health Rep., 54, 1939, 1826, *Rickettsia burnetii*

var. *americana*, Anon., Brit. Med. Jour., 2, 1941, 588; *Rickettsia* (*Coxiella*) *burnetii* Philip, Amer. Jour. Hyg., 37, 1943, 306.) Named for F. M. Burnet who discovered the organism in Australia

microns. Non-motile. Colored purplish with the Giemsa stain, and red against a blue background with the Machiavello stain. Stains well with azur III and methylene blue. Gram-negative.

**Cultivation:** In plasma tissue culture of mammalian cells; on the chorio-allantoic membrane and in the yolk sac of the chick embryo; in rabbit testes and in the endothelial cells overlying Descemet's membrane of the rabbit eye.

**Immunology:** Immunity conferred by infection appears less complete than in typhus and Rocky Mountain spotted fever. Strains from several different areas have been found to cross immunize in guinea pigs, but the true relationship of the disease occurring in different localities remains to be determined. Reciprocal cross-immunity between mite strains and human strains has been demonstrated in rabbits, hamsters and mice.

**Serology:** Antigens from different strains vary in sensitivity when tested by complement fixation with immune sera. There are probably a number of different types on the basis of complement fixation with immune sera. Has a common antigenic factor with *Proteus* OX-K.

**Resistance to chemical and physical agents:** Readily inactivated by heat and chemical agents. Destroyed by a temperature of 50°C for 10 minutes, and by 0.1 per cent formalin and 0.5 per cent phenol.

**Pathogenicity:** Pathogenic for man, monkeys, gibbons, guinea pigs, hamsters, rats, voles, mice, gerbils, rabbits (by intraocular injection) and chick embryo. There is wide variation in the virulence of different strains for laboratory animals, infection being established with great difficulty with some, while others may cause a high mortality.

A febrile reaction occurs in guinea pigs. Passage in guinea pigs and mice is accomplished by inoculation of infected spleen or blood from an infected animal,

passage in rabbits by intraocular inoculation of blood, lymph node or organ emulsions of infected animals. Ascites, enlarged spleen often with a fibrinous deposit are characteristic.

In man an eschar with adenopathy develops at the site of the mite bite. In scrub typhus the eschar is not present. A febrile reaction with exanthema occurs and mortality is variable.

In rabbits infection of Descemet's membrane follows intraocular injection of infected material.

**Source.** Seen by Hayashi in smears and sections of the lesion (eschar) at the site of the mite bite and in smears and sections of the adjacent lymph nodes from cases of the disease; also seen by Nagayo et al. (*loc cit*) in the endothelial cells overlying Descemet's membrane in rabbits inoculated intraocularly with infectious material.

**Habitat.** The mites (*Trombicula akamushi*, *Trombicula deliensis* syn. *T. walchi*, *Trombicula fletcheri* and probably several others). Infective through the ova of the adult female. Only the larvae feed on rodents or man. Reservoir hosts are probably certain wild rodents, including house and field rats, mice and voles and probably some birds. The etiological agent of tsutsugamushi disease and scrub typhus (for numerous other designations of the disease see Farner and Katsampos, U S Naval Med Bull, 43, 1911, 800).

**NOTE.** *Rickettsia nipponica* Sellards. (Sellards, Amer. Jour. Trop. Med, 3, 1923, 515, *Rickettsioides nipponica* da Rocha-Lima, in Kolle and Wasserman, Handb. d. path. Mikroorganismen, 3 Aufl., 8, 1930, 1350.) This problematic organism was thought by its author to be the cause of tsutsugamushi disease. Because it was cultivatable by the methods used by Sellards, it is not now regarded as identical with *Rickettsia tsutsugamushi* Ogata. *Rickettsioides nipponica* is the type species (monotypy) of the

Genus III. *Cowdria* Bengtson, gen. nov.

Named for E. V. Cowdry who first described the organism in heartwater of three ruminants, sheep, goats and cattle.

Small pleomorphic, spherical or ellipsoidal, occasionally rod-shaped organisms, occurring intracellularly in ticks Gram-negative. Have not been cultivated in cell-free media. Parasites which are the etiological agent of heartwater of cattle, sheep and goats.

The type species is *Cowdria ruminantium* (Cowdry) Bengtson.

1. *Cowdria ruminantium* (Cowdry) Bengtson, comb. nov. (*Rickettsia ruminantium* Cowdry, Jour. Exp. Med., 42, 1925, 231; *Rickettsia* (*Cowdria*) *ruminantium* Moshkovsky, Uspekhi Sournemnoi Biologii (Russian) (Advances in Modern Biology), 19, 1945, 18.) From M. L. Ruminantia, the cud-chewing mammals

Differ morphologically from typical rickettsiae, showing usually spherical and ellipsoidal forms, occasionally bacillary forms. Irregular pleomorphic forms occur. Grow in the cytoplasm of cells, sometimes in densely packed masses. Size of cocci from 0.2 to 0.5 micron in diameter in the endothelial cells of animals, 0.2 to 0.3 micron in diameter in ticks. Bacillary forms 0.2 to 0.3 by 0.4 to 0.5 micron and pairs 0.2 by 0.8 micron in ticks. Non-motile.

Stain blue with the Giemsa stain and can also be stained by methylene blue and other basic aniline dyes. Gram-negative.

Cultivation not reported.

Immunology. Immunity incomplete after recovery from the infection. The organisms are found in the tissues long after recovery. There is some evidence of a variety of strains.

Pathogenicity. Pathogenic for goats, sheep and cattle. Transmissible to goats by inoculation of infected blood intrajugularly. The most characteristic lesion is the hydropericardium of infected animals. The only small animal shown to be susceptible is the ferret.

Source: Seen in the endothelial cells of renal glomeruli and in the endothelial cells of the cerebral cortex of animals suf-

fering from heartwater and in the tick, *Amblyomma hebraeum*.

Habitat: The bont tick (*Amblyomma hebraeum*) and also *Amblyomma variegatum*. When the tick is infected in the larval state, it can transmit the infection to the nymphal and adult stages, but the disease is not transmissible through the ova of the adult female tick. The etiological agent of heartwater in sheep, goats and cattle in South Africa.

Appendix I: Further studies of the organism of trench fever are required before the relationship of *Rickettsia quintana* to the other more firmly established species of rickettsiae can be determined. Therefore, it is placed in this appendix.

1. *Rickettsia quintana* Schminke. (Schminke, Münch. med. Wchnschr., 64, July 17, 1917, 961; *Rickettsia wolhynica* Jungmann and Kuczynski, Ztschr. klin. Med., 85, 1918, 261; *Fossilis quintana* suggested as a possible subspecies "if necessary" by Megaw, Trop. Dis. Bull., 40, 1943, 828.)

Probable synonym: *Rickettsia pediculi* Munk and da Rocha-Lima, Münch. med. Wchnschr., 64, 1917, 1423.

Coccoid or ellipsoidal organisms, often occurring in pairs, more plump and staining more deeply with the Giemsa stain than *Rickettsia prowazekii*. Da Rocha-Lima gives their size as 0.2 to 0.4 micron by 0.3 to 0.5 micron. In lice appear as short rods, frequently in pairs and often bipolarly stained. Non-motile.

Stain reddish-violet with the Giemsa stain. Gram-negative. Occur extra-

Small bacterium-like, pleomorphic organisms varying in size from coccoid forms to well marked rods. Occur as cytoplasmic micro-colonies with diffuse or compact distribution of the organisms through the cytoplasm. Also seen extracellularly, where they appear as small lanceolate rods, diplobacilli and occasionally segmented filamentous forms. Chains of 3 to 6 elements often seen. Quite uniform in size and morphology in infected yolk sacs and in mouse spleen with exceedingly minute forms in heavily infected material. Small lanceolate rods, 0.25 by 0.4 to 0.5 micron, bipolar forms 0.25 by 1.0 micron, diplobacilli 0.25 by 1.5 microns. Non-motile.

With Giemsa's stain they appear reddish-purple, with Machiavello's stain bright red against a blue background. Gram-negative.

Cultivation: May be cultivated in plasma tissue cultures, in modified Maitland media and in the yolk sac of chick embryos.

Immunology: There is complete cross immunity between Australian and American strains of Q fever in guinea pigs. Strains from other parts of the world also cross immunize.

Serology: American and Australian strains are identical by agglutination and agglutinin absorption. Strains from various countries are serologically related as shown by complement fixation. Q fever is distinguishable from other rickettsial diseases by complement fixation tests. No common antigenic factor with any *Proteus* strain has been demonstrated.

Filterability: The infectious agent of Q fever readily passes Berkefeld N filters which are impermeable to ordinary bacteria and W filters which are impermeable to typhus and spotted fever rickettsiae.

Resistance to chemical and physical agents: Comparatively resistant to heat, drying and chemical agents. Survives at least 100 days in cell free media with

out loss of titer, resistant to 60°C for 1 hour and to 0.5 per cent formalin and 1 per cent phenol when tested in fertile eggs.

Pathogenicity: Pathogenic for man, guinea pig and the white mouse. The monkey, dog, white rat and rabbit are mildly susceptible. Certain bush animals in Australia, particularly the bandicoot, are susceptible and these animals have been found naturally infected. Other rodents and marsupials are mildly susceptible. Calves have been experimentally infected and cows have been found recovered from naturally acquired infections.

A febrile reaction occurs in guinea pigs but mortality is low except with heavily infected yolk sac which causes a high mortality. On subcutaneous or intradermal inoculation a marked inflammatory thickening of the skin occurs at the site of inoculation. On autopsy the spleen is enlarged from 2 to 12 times by weight and is engorged with blood. Transfer in guinea pigs and mice is accomplished by transfer of infected liver and spleen. A febrile reaction often accompanied by pneumonitis occurs in man, but mortality is low.

Source: First seen in smears from mice inoculated intraperitoneally with infectious material by Burnet and Freeman (Med Jour Australia, 2, 1937 (2), 231).

Habitat: The wood tick (*Dermacentor andersoni*) and the ticks, *Dermacentor occidentalis*, *Amblyomma americanum*, *Haemaphysalis leporis-palustris*, *Ixodes dentatus* and *Haemaphysalis humerosa*. Several other species of ticks have been shown to transmit experimentally the virus of Q fever. It has been found to survive in the ova of the female ticks (*Dermacentor andersoni* and *Haemaphysalis humerosa*). The Landcrot (*Isodon macrurus*) is probably the natural reservoir of the disease in Australia. The etiological agent of Q (Queensland) fever in man.

rend. Soc. Biol., Paris, 126, 1937, 382; *Ehrlichia canis* Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), 19, 1915, 18.) Moshkovsky selects this species as the type species of the subgenus *Ehrlichia* Moshkovsky (*loc. cit.*). Found in dogs used for experimental purposes in Algeria. Appears to be transmitted naturally by the dog tick (*Rhipicephalus sanguineus*). All active stages of the tick transmit the organism and it passes intraovarially from the female to the larvae of the next generation. The organisms are generally spherical in shape and can be seen in the circulating monocytes. The infection causes a serious and often fatal illness in dogs. Small laboratory animals are not susceptible to the disease.

*Rickettsia conjunctivae*, *Rickettsia conjunctivae bovis* and *Rickettsia conjunctivae galli*, see Family III, Chlamydozoaceae.

*Rickettsia ctenocephali* Sikora. (Arch. Schiffs- u. Tropenhyg., 22, 1918, 442.) Found in cat fleas (presumably *Ctenocephalides felis*) on the surface of the organs in the body cavity and in the coelomic fluid. Two forms were found which might be two species, one resembling *Rickettsia pediculi* and the other *Rickettsia melophagi*. Hertig and Wolbach (Jour. Med. Res., 44, 1921, 329) found *Rickettsia ctenocephali* to vary in size and shape from minute cocci to rather large, swollen, curved rods, staining reddish with the Giemsa stain.

*Rickettsia culicis* Brumpt. (Ann. Parasitol. Hum. et Comp., 16, 1938, 153.) Found in the stomach epithelium of mosquitoes (*Culex fatigans*) 12 days after they had been fed on a patient carrying *Microfilaria bancrofti*. Thought to be pathogenic for the mosquito and possibly for man. Occurs in the form of small granules and more often as small bipolar rods. Stains with haemalum, erythrosine-orange and toluidine blue. Gram-negative.

*Rickettsia dermatophila* Steinhaus. (Pub. Health Repts., 67, 1942, 1375.) Found in all stages of the wood tick (*Dermacentor andersoni*). In the epithelial cells of the intestinal diverticula and other tissues of the tick, usually extracellularly but sometimes intracellularly. Not seen in the nuclei of cells. Gram-negative and staining red with the Machiavello stain, and bluish-purple with the Giemsa stain. Stains less deeply with ordinary bacterial stains than most bacteria. Resembles *Rickettsia rickettsii* morphologically but is slightly larger. Not pathogenic for laboratory animals or for some of the natural hosts of *Dermacentor andersoni*.

*Rickettsia hirundinis* Cowdry. (Jour. Exp. Med., 37, 1923, 431.) An organism observed by Arkwright, Atkin and Bacot (Parasitology, 15, 1921, 27) in the tissues of *Cimex hirundinis* which is probably the same organism to which Cowdry referred as *Rickettsia hirundinis*. Considered by Steinhaus as a *nomen nudum*.

*Rickettsia kairo* da Rocha-Lima. (Cairo rickettsia, Arkwright and Bacot, Brit. Jour. Exper. Path., 4, 1923, 70; da Rocha-Lima, in Kolle and Wasserman, Handb. d. path. Mikroorg., 3 Aufl., 8, 1930, 1361.) Resembles *Rickettsia rochalimae* and *Rickettsia prowazekii*.

*Rickettsia lectularia* Arkwright, Atkin and Bacot. (Parasitology, 15, 1921, 27.) Found in the gut of the bedbug (*Cimex lectularius*) as filamentous and rod-shaped organisms. It seems probable that all bedbugs harbor the organism and it is also present in the developing ova. The location is intracellular. Very pleomorphic, ranging from small coccoid forms to thread-like forms. The small coccoid and diplococcoid forms stain deep purple with the Giemsa stain, while bacillary, lanceolate and thread forms stain more red than purple with the Giemsa stain. Not infective for small laboratory animals or for man.

*Rickettsia linognathi* Hindle. (Parasitology, 15, 1921, 152.) Found in the

cellularly in the region of the epithelial lining of the gut of the louse.

**Cultivation:** Has not been cultivated in tissue culture or any cell-free medium, though *Rickettsia pediculi*, considered by some identical with *Rickettsia quintana*, has been cultivated on human and horse blood agar.

**Pathogenicity.** Pathogenic for man, causing recurrent fever. No strain has been definitely established in laboratory animals.

**Immunology.** Partial immunity is produced after an attack of the disease. The disease is characterized by relapses which may occur as long as two years after the initial attack.

**Distinctive characteristics:** The organism resists a temperature of 60°C moist heat for 30 minutes or a dry heat at 80°C for 20 minutes. It resists desiccation in sunlight for 4 months. It is filterable under certain conditions but not when in plasma or serum. It is present in filtrates of infected vaccine sediments and excrements of infected lice.

**Source:** Seen in lice fed on trench fever patients by Topfer (Münch med Wehnscr., 61, 1916, 1495).

**Habitat:** The epithelial lining of the gut of the body louse (*Pediculus humanus* var. *corporis*) where they occur extracellularly, and *Pediculus capitis*. The virus is not transmissible through the ova. May be the etiological agent of trench fever (Wolhynian fever, shin bone fever, five-day fever).

**Appendix II:** Additional named species are included in Chapter V, *Rickettsiae*, in Steinhaus, *Insect Microbiology* (Ithaca, 1916, 304-328). Some differ morphologically and tinctorially from typical rickettsiae, some are not associated with an arthropod vector, some have been incompletely studied and described, some have been cultivated in cell-free media. Pending the completion of further studies involving possible

cultivation in fertile eggs, the determination of biological properties, and adequate comparative immunological and serological studies, no attempt is made to classify these organisms. The descriptions are condensed from those given by Steinhaus:

*Ehrlichia (Rickettsia) kurlovi* Moshkovsky. (Compt. rend. Soc. Biol., Paris, 126, 1937, 379; *Ehrlichia kurlovi* Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), 19, 1945, 12.) Found in the monocytes of guinea pigs. Described by Kurloff in 1889 as inclusions in the mononuclear cells of guinea pigs and other animals. These became known as Kurloff bodies. However, the parasitism of these bodies is questionable.

*Rickettsia arium* Carpano. (Riv. Pat. Comp., Jan-Feb., 1936, 1.) Minute bodies in the leucocytes and tissue cells of a bullfinch (*Pyrrhula europaea*) brought to Egypt from Germany. Donatien and Lestoquard (Arch. Inst. Pasteur Algérie, 15, 1937, 142) suggested that this organism might have been that of psittacosis.

*Rickettsia bovis* Donatien and Lestoquard. (Donatien and Lestoquard, Bull. Soc. Path. Exot., 29, 1936, 1057; *Ehrlichia bovis* Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), 19, 1945, 18.) Concerned in a disease of cattle which is transmitted by an unidentified tick of the genus *Hyalomma*. The organism occurs in circular or round angled polygonal masses which consist of a large number of tightly pressed, minute spherical granulations. These masses are situated in the cytoplasm of various monocytes. The organism causes a relatively light febrile disease in cattle, and an inapparent infection in sheep and fever in monkeys.

*Rickettsia canis* Donatien and Lestoquard. (Donatien and Lestoquard, Bull. Soc. Path. Exot., 28, 1935, 418; *Ehrlichia (Rickettsia) canis* Moshkovsky, Compt.

*rocha-limae*. It causes a febrile illness in man in which relapses occurred 3 to 5 times as in trench fever. *Rickettsia weigli* was agglutinated by convalescent sera but not by sera from typhus patients. Convalescent sera gave no positive Weil-Felix reaction.

*Wolbachia pipientis* Hertig. (*Rickettsia* of *Culex pipiens*, Hertig and Wolbach, Jour. Med. Res., 44, 1924, 329; Hertig, Parasitology, 28, 1936, 453.) This is the type species of the genus *Wolbachia* Hertig (*loc. cit.*). Found in the ovaries or testes of the mosquito, and present in all stages of the mosquito's development. The outstanding morphological characteristic of the organism is great pleomorphism. Minute coccoids and short rods may be considered typical, but the usual microscopic field consists of various shapes and sizes. Some forms show bipolar staining with the Giemsa stain. The organism is a harmless parasite of the mosquito. Laboratory animals are apparently not susceptible.

The following unnamed rickettsiae isolated from animals or seen in animals are included in Steinhaus' list of rickettsiae (Insect Microbiology Ithaca, 1946, 341).

A rickettsia was isolated by Parker, Kohls, Cox and Davis (Pub Health Rept., 54, 1939, 1482) from a tick (*Amblyomma maculatum*). It is pathogenic for guinea pigs and the disease is referred to as the maculatum disease. There is complete cross immunity in guinea pigs between this infection and Rocky Mountain spotted fever and boutonneuse fever, but it differs from these diseases in some particulars.

A rickettsia-like organism was isolated from the reduviid bug (*Triatoma rubrofasciata*) by Webb (Parasitology, 52, 1940, 355). It was pathogenic for some laboratory animals and was maintained in guinea pigs for 5 passages. The rickettsiae were transmissible to the

next generation through the egg of the reduviid bug.

A spotted fever type of rickettsia was isolated by Anigstein and Bader (Texas Repts. Biol. Med., 1, 1943, 105) from the dog tick (*Rhipicephalus sanguineus*), taken from normal dogs. It was pathogenic for rabbits and guinea pigs.

A rickettsia was isolated by Anigstein and Bader (Texas Repts. Biol. Med., 1, 1943, 298, 389) from ticks (*Amblyomma americanum*) collected in Texas. They believed it to be the cause of hollis fever.

Rickettsiae were observed by Enigh (Berl. u. Munch. Tierärztl. Wchnschr., 1942, 25) in the leucocytes of a bison calf. No arthropod was associated with this rickettsia.

A rickettsia-like agent pathogenic for guinea pigs was reported by Tatlock (Proc. Soc. Exp. Biol. and Med., 57, 1944, 95). The animals had been injected with blood from a patient with "pretibial" fever. No arthropod vector was indicated.

Three species of rickettsia-like organisms isolated from the wood-tick (*Dermacentor andersoni*) are described by Noguchi (Jour. Exper. Med., 43, 1926, 518-521). These were named *Bacillus rickettsiformis*, *Bacillus pseudoxerosis* and *Bacillus equidistans*. All could be cultivated on cell-free media and none was pathogenic for laboratory animals.

#### Appendix III: Unnamed rickettsia-like organisms seen in the tissues of insects

Hertig and Wolbach (Jour. Med. Res., 44, 1924, 329) list sixteen species of arachnids and twenty-three species of insects which are hosts to rickettsiae or rickettsia-like organisms.

Wolbach (Jour. Amer. Med. Assoc., 84, 1925, 723) reports hosts of non-pathogenic rickettsiae which include fourteen species of arachnids (ticks, mites and spiders) and twenty-two species of insects distributed in nine orders, including

alimentary tract of the goat louse (*Lanognathus stenopsis*). Resembles *Rickettsia trichodectae* morphologically and occurs only extracellularly in the lumen of the gut

*Rickettsia melophagi* Nöller (Arch Schiffs- u Tropenhyg., 21, 1917, 53) Found upon and in the cuticular layer covering the epithelium of the midintestine of the sheep tick (*Melophagus ovinus*). Occurs characteristically in pairs of fairly uniform size, coccoid and sometimes rod-shaped. Gram-negative but stains fairly well with carbol-fuchsin and gentian violet. Stains deep purple with Giemsa's method and bright red with Machiavello's method. Has been cultivated on non-living culture media, a glucose-blood-bouillon agar medium. The ability of *Rickettsia melophagi* to infect sheep has been the subject of contradictory claims. Small laboratory animals seem not to be susceptible.

*Rickettsia ovina* Lestoquard and Donatien. (Lestoquard and Donatien, Bull. Soc. Path. Exot., 29, 1936, 108, *L'Archieve ovine* Moshkovsky, Usphekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), 19, 1945, 18) Found in the blood of diseased sheep from Turkey and Algeria. The organisms occur as minute coccoid granules, grouped in masses and present only in the monocytes and never in endothelial cells. They stain uniformly dark red with the Giemsa stain but did not stain with the Castañeda technic. Infected ticks (*Rhipicephalus bursa*) are thought to be the vectors.

*Rickettsia pisces* Mohamed (Ministry Agr., Egypt., Tech. Sci. Serv. Bull. 214, 1939, 6 pp) In the monocytes and plasma of the blood of a fish (*Tetraodon fahaka*) showing necrotic ulcers on its head and both sides of the body. The heart, liver and intestines showed lesions. The organisms were minute coccoid forms varying from 0.2 to 0.4 micron in diameter and frequently occurring in pairs.

*Rickettsia rocha-limae* Weigl. (Przegląd. Epidemiol., 1, 1921, 375) Occurs in lice (*Pediculus humanus*) but is apparently non-pathogenic either to lice or to vertebrates. Larger and more pleomorphic than *Rickettsia prowazekii*. In smears or sections of the gut of lice, *Rickettsia rocha-limae* occurs in agglomerated masses, grouped like staphylococci. They occur both extracellularly and intracellularly and stain more deeply than *Rickettsia prowazekii*. Weigl claims to have cultivated this species on artificial culture media under anaerobic conditions. Not pathogenic for laboratory animals or man.

*Rickettsia suis* Donatien and Gayot. (Bull. Soc. Path. Exot., 35, 1942, 324) Causes a disease in swine, the pathology of which resembles heartwater of ruminants. See Genus III, *Cowdria*, Family *Rickettsiaceae*.

*Rickettsia trichodectae* Hindle. (Parasitology, 13, 1921, 152) In the species of biting lice (*Trichodectes pilosus*) which may be found on horses. This insect does not suck blood. The organisms occur extracellularly in the alimentary tract of the louse. The average size is 0.3 to 0.5 by 0.5 to 0.9 micron and occasionally longer forms occur.

*Rickettsia weigli* Masing (Arch. Inst. Pasteur, Tunis, 25, 1936, 373) Concerned in an epidemic disease which broke out in 1931 among employees of the Institute of Biology in Łódź who were engaged in feeding supposedly uninfected lice on their persons. Masing and others have suggested the possibility that this rickettsia may be an extreme mutant of *Rickettsia pediculi*. Small coccoid to rod shaped organisms staining well with the Giemsa stain, usually slightly longer than *Rickettsia prowazekii*. In the louse (*Pediculus humanus*), the rickettsiae occur extracellularly in the intestinal lumen forming a layer covering the surface of the epithelial lining. Not pathogenic for the louse as is *Rickettsia prowazekii* and *Rickettsia*

## FAMILY II. BARTONELLACEAE GIESZCZYKIEWICZ.\*

(Bull. Intern. Acad. Polon. Sci., Classe Sci. Math. Nat., B (I), 1939, 9-30.)\*\*

Small, often pleomorphic, rod-shaped, coccoid, ring-shaped, filamentous and beaded micro-organisms, staining lightly with aniline dyes, but well with Giemsa's stain. Gram-negative. Parasites of the erythrocytes in man and other vertebrates. Known to be transmitted by arthropod vectors in some cases. The causative organisms of bartonellosis in man, haemobartonellosis, grahamellosis and eperythrozoonosis in the lower animals. Differ from the protozoa that also parasitize erythrocytes in that the entire parasite stains with no differentiation into cytoplasm and nucleus.

## Key to the genera of family Bartonellaceae.

1. Parasites of the erythrocytes and of fixed tissue in man.  
Genus I. *Bartonella*, p. 1100
2. Parasites of the erythrocytes of lower mammals, increased in susceptible animals by splenectomy. Eradicated by arsenicals.  
Genus II. *Haemobartonella*, p. 1102
3. Parasites of the erythrocytes of lower mammals. Not increased in susceptible animals by splenectomy. Not eradicated by arsenicals.  
Genus III. *Grahamella*, p. 1103
4. Blood parasites, found on the erythrocytes and in the plasma of lower mammals. Appear as rings, coccoids and short rods. Splenectomy activates latent infections.  
Genus IV. *Eperythrozoon*, p. 1111.

Genus I. *Bartonella* Strong, Tyzzer and Sellards.

(*Bartonella* Strong, Tyzzer, Brues, Sellards and Gastiaturó, Jour. Amer. Med. Assoc., 61, 1913, 1715, not *Bartonella* Mühlenberg, in Willdenow, Neue Schrift Ges. Nat. Fr., Berlin, 3, 1801, 444; not *Bartonella* Sims, Bot. Mag., 1804, not *Bartonella* Crossman, Essais de Paléontologie Comparée, 4me Livr., Paris, 1901; Strong, Tyzzer and Sellards, Jour. Amer. Med. Assoc., 64, 1915, 808; emend. Tyzzer and Weinman, Amer. Jour. Hyg., 30 B, 1939, 143) Named for A. L. Barton who described these organisms in 1909.

Parasites of the erythrocytes which also multiply in fixed tissue cells. On the red blood cells in stained films, they appear as rounded or oval forms or as slender, straight, curved or bent rods occurring either singly or in groups. Characteristically in chains of several segmenting organisms, sometimes swollen at one or both ends and

\* Prepared by Dr. Ida A. Bengtson (retired), National Institute of Health, Bethesda, Maryland and Dr. David Weinman, Parasitologist to the 1937 Harvard Expedition to Peru, Boston, Mass., April, 1947.

\*\* Partial syn. *Anaplasmatidae* has been proposed as a family name to unite the four genera *Anaplasma*, *Grahamella*, *Bartonella* and *Eperythrozoon* by Neitz, Alexander and du Toit (Onderst. Jour. Vet. Sci. and An. Ind., 3, 1934, 268). Since the name is derived from *Anaplasma*, the nature of which is not fully understood and since these authors consider the 4 genera as belonging to the protozoan order Haemosporidia, it seems advisable not to consider this nomenclature for the present. The genus *Anaplasma* (parasites of the red blood cells of cattle) created by Theiler (Transvaal Govt. Vet. Bact. Rept. 1908-9, 7-64, 1910) consists of two species *Anaplasma marginale* and *Anaplasma centrale*. Recent workers are inclined to consider them to be bacterial in nature as they do not show a differentiation into cytoplasm and nucleus.

numerous non-blood-sucking insects as well as lice and ticks.

Cowdry (Arch Path and Lab Med, 2, 1926, 59) lists seven species of arachnids and twenty-four species of insects which are hosts to non-pathogenic rickettsiae.

Buchner, P. (Tier und Pflanze in Symbiose. Gebrüder Borntraeger, Berlin, 1930, 900 pp) Through the text, and particularly on pages 300-664, the rickettsia-like and bacterium-like microorganisms occurring intracellularly in

insects and other small animals are discussed, principally from the viewpoint of the biologist

Paillot, A (L'infection chez les Insectes, Paris, 1933, 535 pp) Concerned principally with bacterial infections of insects, but also includes information in intracellular symbiotes and rickettsia-like and bacterium-like microorganisms.

Steinhaus, Edward A. (Insect microbiology Ithaca, 1946, 188-255) Intracellular bacterium-like and rickettsia-like symbiotes are discussed

    - 148. *Pseudomonas wieringae*.

frequently beaded (Strong et al, *loc cit*, 1913), without a distinct differentiation of nucleus and cytoplasm. In the tissues they are situated within the cytoplasm of endothelial cells as isolated elements and grouped in rounded masses. These parasites occur spontaneously in man and in arthropod vectors, are endowed with independent motility, reproduce by binary fission, and may be cultivated by unlimited serial transfers on cell-free media. One species has been recognized. It is known to be established only on the South American continent and perhaps in Central America. Human bartonellosis may be manifested clinically by one of the two syndromes constituting Carrión's disease (Oroya fever or verruga peruana) or as an asymptomatic infection (definition by Strong, Tyzzer and Sellards *emend.* Tyzzer and Weinman (in Weinman, Trans. Amer. Philosoph. Soc., N.S., 33, pt. 3, 1944, 216).

The type species is *Bartonella bacilliformis* (Strong et al.) Strong et al.

1. *Bartonella bacilliformis* (Strong, Tyzzer, Bruce, Sellards and Gastiaturú) Strong, Tyzzer and Sellards (*Bartonella bacilliformis* Strong et al., Jour. Amer. Med. Assoc., 61, 1913, 1715; *Bartonella bacilliformis* Strong, Tyzzer and Sellards, Jour. Amer. Med. Assoc., 64, 1915, 808, *emend.* Tyzzer and Weinman, Amer. Jour. Hyg. 30(B), 1939, 143, also see Weinman, Trans. Amer. Philosoph. Soc., N.S., 33, pt. 3, 1944, 216. Partial or complete synonyms: *Bartonella cocoide* (sic) Herceles, Ann. de l'Ac. de Med., Lima, 9, 1926, 231, *Bartonella peruviana* Escamé, Bull. Soc. path. Exot., 22, 1929, 351, *Eperithyrozoon noguchii* Lwoff and Vaucl, Compt. rend. Soc. Biol., Paris, 103, 1930, 975.) From Latin *bacillus*, rod and *forma*, shape.

Small, pleomorphic organisms, showing greatest morphological range in the blood of man, appearing as red-violet rods or coccoids situated on the red cells, when stained with Giemsa's stain. Bacilliform bodies are the most typical, measuring 0.25 to 0.5 by 1 to 3 microns. Often curved and may show polar enlargement and granules at one or both ends. Rounded organisms measure about 0.75 micron in diameter and a ring-like variety is sometimes abundant. On semi-solid media a mixture of rods and granules appear. The organisms may occur singly or in large and small, irregular dense collections, measuring up to 25 microns or more in length. Puncti-

form, spindle-shaped and ellipsoidal forms of the organism occur, varying in size from 0.2 to 0.5 by 0.3 to 3 microns.

Gram-negative and non-acid-fast. Stain poorly or not at all with the usual aniline dye stains, but satisfactorily with Romanowsky and Giemsa stains.

Motile in the blood and in cultures. One to four unipolar flagella.

Cultivation: Growth in semi-solid agar with fresh rabbit serum and rabbit hemoglobin and in semi-solid agar with blood of man, horse or rabbit with or without the addition of fresh tissue and certain carbohydrates, in other culture media containing blood, serum or plasma, Hinton's hormone agar at 20 per cent, semi-solid gelatin media, blood-glucose-cystine agar, chorio-allantoic fluid and yolk sac of chick embryo.

Gelatin not liquefied.

No acid or gas on glucose, sucrose, galactose, maltose, fructose, xylose, lactose, mannose, mannitol, dulcitol, arabinose, raffinose, rhamnose, dextrin, inulin, salicin and amygdalin.

No action on lead acetate.

Aerobic, obligate.

Optimum temperature 28°C.

Immunology: Natural immunity to infection has not been demonstrated in susceptible species. Acquired immunity apparent both during and after the disease. Bartonellae from different sources appear to provoke similar responses. Bartonellae from Oroya fever protect

against infection with organisms obtained from verruga cases.

**Serology:** Immune sera fix complement and agglutination of suspensions of *Bartonella* by sera from recovered cases has been reported.

**Pathogenicity:** Three forms of the disease occur in man; the anemic (Oroya fever), the eruptive (verruca peruana) and mixed types of both of the other forms. Experimental Oroya fever has not been successfully produced in ani-

mals, except rarely in an atypical form in monkeys. Experimental verruca peruana has been produced in man, in a number of species of monkeys and occasionally in dogs.

**Source:** Blood and endothelial cells of lymph glands, spleen and liver of human cases of Oroya fever.

**Habitat:** Blood and endothelial cells of infected man, probably also in sand flies (*Phlebotomus verrucarum* and *Phlebotomus noguchii*).

### Genus II. *Haemobartonella* Tyzzer and Weinman.

(Amer. Jour. Hyg., 30(B), 1939, 341.) From Greek *haemos*, blood and the generic name *Bartonella*.

Includes parasites of the red blood cells in which there is no demonstrable multiplication in the tissues and which do not produce cutaneous eruptions. They are typically rod- or coccoid-shaped, showing no differentiation into nucleus and cytoplasm, occurring naturally as parasites of vertebrates, and are transmitted by arthropods. They are distributed over the surface of the erythrocytes, and possibly sometimes within them. They stain well with Romanowsky type stains and poorly with other aniline dyes. Gram-negative. Not cultivated indefinitely in cell-free material. Rarely produce disease in animals without splenectomy, are markedly influenced by arsenotherapy, and are almost all of world-wide distribution. The experimental host range is restricted, infectivity of a rodent species for other rodents being common, but for primates unknown.

The type species is *Haemobartonella muris* (Mayer) Tyzzer and Weinman.

#### Key to the species of genus *Haemobartonella*.

- I The etiological agent of haemobartonellosis of the white rat.
  1. *Haemobartonella muris*.
- II. The etiological agent of haemobartonellosis of the dog.
  2. *Haemobartonella canis*.
- III. The etiological agent of haemobartonellosis of the vole.
  3. *Haemobartonella microfilii*.
- IV. The etiological agent of haemobartonellosis of the guinea pig.
  4. *Haemobartonella tyzzeri*.
- V. The etiological agent of haemobartonellosis of cattle.
  5. *Haemobartonella bovis*.
- VI. The etiological agent of haemobartonellosis of the buffalo.
  6. *Haemobartonella sturmanii*.
- VII. The etiological agent of haemobartonellosis of the deer mouse.
  7. *Haemobartonella peromyscii*.
- VIII. The etiological agent of haemobartonellosis of the gray-backed deer mouse.
  - 7a. *Haemobartonella peromyscii var. maniculati*.
- IX. The etiological agent of haemobartonellosis of the short-tailed shrew.
  8. *Haemobartonella blarinae*.
- X. The etiological agent of haemobartonellosis of the gray squirrel.
  9. *Haemobartonella sciurii*.

1. *Haemobartonella muris* (Mayer) Tyzzer and Weinman. (*Bartonella muris* Mayer, Arch. f. Schiffs.-u. Tropenhyg., 25, 1921, 151; *Bartonella muris ratti* Regendanz and Kikuth, Compt rend Soc. Biol., Paris, 98, 1928, 1578; Tyzzer and Weinman, Amer. Jour. Hyg., 30(B), 1939, 143.) From Latin *mus*, *muris*, mouse.

Slender rods with rounded ends, frequently showing granules or swellings at one or both extremities, and dumbbell, coccoid or diplococcoid forms. May occur individually, in pairs, or in short chains of 3 or 4 elements, and, when abundant, in parallel grouping. The rods measure 0.1 by 0.7 to 1.3 microns and as much as half the length of a red cell. The coccoids have a diameter of 0.1 to 0.2 micron.

They have been found on and in the erythrocytes and in the plasma. Preferred stains are those of the Romanowsky type. With Giemsa's stain various investigators report an intense red coloration, a bluish tinge with distinct pink shading, blue with purple granules. With Wright's stain, the organisms stain bluish, with reddish granules at the ends. With Schilling's methylene blue-eosin stain the organisms stain a bright red color with the erythrocyte staining blue. They stain faintly with Manson's stain, pyronin-methyl green and fuchsin. Gram-negative.

There is lack of agreement concerning visibility in the fresh state and motility. Various authors report Brownian movement, slow and sinuous motion in the red cell or rapid motion.

Cultivation: Cultivated with difficulty and divergent results have been reported. Growth on various media reported (blood agar, agar with 2 per cent defibrinated rat blood, horse blood agar, N. N. N., Blutrösplatte of Wethmar, hormone agar with blood of rabbit, horse or man, ascitic fluid agar, chocolate agar, semi-solid rabbit serum agar, semi-solid rabbit blood agar, Noguchi-Wenyon medium, defibrinated rat blood, glucose broth,

Tarozzi broth, peptone water) but usually growth was scant or could not be continued by transfer to the same medium or the organism isolated was non-infectious or the possibility of latent infections in the animal was not excluded. Best results are apparently obtained with semi-solid rabbit serum agar and semi-solid rabbit blood agar.

No conclusive results have been reported in tissue culture. The organism has been cultivated on the chorio-allantoic membrane of the chick embryo.

Filterability: Non-filterable with Seitz or Berkefeld N filters.

Immunology: No authentic case of true natural immunity in rats has been established. Acquired immunity occurs in (1) the latently-infected rat, (2) the infected rat after splenectomy and recovery from the disease, the period of resistance corresponding to the duration of latency, (3) the non-splenectomized non-carrier rat following infection, (4) animals other than the rat following infection.

Serology: No precipitins, thrombocytobarin, isoagglutinins, or cold hemolysins have been reported in the serum of anemic rats. Complement deviation and agglutination have been reported with sera from rabbits, rats and guinea pigs injected with cultures. Rabbits immunized with cultures have given positive Weil-Felix reactions with *Proteus* OX19 and OXK and rat sera recovered from haemobartonellosis have given a positive Weil-Felix reaction and positive agglutination in low dilution with *Rickettsia prowazekii*.

Pathogenicity: Infected blood, liver suspension, defibrinated laked blood, washed red cells, plasma and hemoglobinuric urine may produce infection by the subcutaneous, intravenous, intraperitoneal or intracardiac routes. Slight, transient or no haemobartonellosis occurs in adult non-splenectomized haemobartonella-free albino rats, adult non-splenectomized albino rats of carrier stock, adult splenectomized rats pre-

viously infected, until 15 weeks to 8 months after infection. Typical haemobartonellosis occurs in adult splenectomized haemobartonella-free albino rats and in young non-splenectomized haemobartonella-free albino rats weighing 20 to 30 grams at 3 weeks. Variable results have been obtained by different investigators with wild mice, guinea pigs, rabbits, hamsters, pigeons and monkeys (*Macacus rhesus* and *Macacus sp.*). It is known to be infectious for wild rats, albino mice, rabbits and for two Palestinian rodents (*Sphallax* (*Spalax* correct designation) *typhlops* and *Meriones tristrami*). Negative results have been reported in dogs, kittens, cats, sheep and various birds. Causes a definite and characteristic anemia without cutaneous eruption.

**Arsenical therapy:** True sterilization of latent or recognized infection with organic arsenical compounds.

**Source:** Blood of infected albino rats.

**Habitat:** Ectoparasites such as the rat louse (*Polyplox* (*Haematopinus*) *spinulosus*), the flea (*Xenopsylla cheopis*) and possibly the bedbug (*Cimex lectularius*). Also found in the erythrocytes of susceptible animals. World wide in distribution.

**2. Haemobartonella canis** (Kikuth) Tyzzer and Weinman. (*Bartonella canis* Kikuth, Klin. Wehnschr., 1928, 1729; Tyzzer and Weinman, Amer. Jour. Hyg., 50(B), 1939, 151.) From Latin *canis*, dog.

One of the most pleomorphic of the haemobartonellae, occurring as thin rods, straight or slightly curved, dumbbell-shaped organisms, dots, coccoids, or rings. Chains of rods, coccoids or rings occur. These consist of only one type of these forms or a mixture of types. The chains may be straight, curved, branched or annular. Variable in size. Round forms vary from 0.2 or 0.5 micron to the limit of visibility. Single rods are 0.2 by 1 to 5 microns, while the

composite forms vary from 1 to 4 microns. Situation is epi-erythrocytic.

Giemsa's fluid stains the organism red-violet, usually intensely. Methylene blue used as a vital stain colors the organism distinctly. Gram-negative and non-acid-fast.

Considered non-motile by most investigators.

**Cultivation:** Cultivation has not been demonstrated in semi-solid rabbit serum-agar medium nor in media containing serum of splenectomized dogs, N.N.N., Noguchi's medium for leptospira, blood broth, Chatton's medium covered with vaseline for *Trichomastix*.

**Filterability:** Results equivocal.

**Immunology:** The outstanding phenomena resemble those found in the rat infected with *Haemobartonella muris*.

**Pathogenicity:** Splenectomy is essential to infection accompanied by anemia in the dog. Negative results in splenectomized haemobartonella-free guinea pig, rat, rabbit, and monkey (*Cercopithecus sabaeus*). No infection or anemia in unoperated mice, white rats, young rabbits, young dogs and young guinea pigs. The splenectomized cat has been found to carry the infection by serial passage.

**Arsenical therapy:** Complete sterilization obtained by neocarsphenamine.

**Source:** Erythrocytes of infected splenectomized dogs.

**Habitat:** Found in dog fleas (*Ctenocephalus*) and erythrocytes of infected animals. Distribution wide-spread, the infection occurring spontaneously in Europe, India, North and South Africa, North and South America.

**3. Haemobartonella microfil** Tyzzer and Weinman. (Tyzzer and Weinman, Amer. Jour. Hyg., 50(B), 1939, 143, also see Weinman, Trans. Amer. Philosoph. Soc., N. S., 33, 1944, 312; questionable synonym *Bartonella arvicolae* Yakimoff, Arch. Inst. Past. de Tunis, 17, 1928, 330; *Haemobartonella arvicolae* Weinman, loc.

cit., 290) From the genus of voles, *Microtus*.

In infected animal, morphology resembles that of *Haemobartonella canis*, the organisms occurring as rods, coccoids, filaments, club forms, ring forms and granular masses. In addition to these forms there occur in Giemsa-stained blood films ovoids, diamond- or flame-shaped small forms as well as coarse segmented or unsegmented filaments up to 5 microns in length. Filaments may contain one or more rings, or may be composed in part or entirely of diamond-shaped, coccoid or ovoid elements, sometimes in parallel rows. Rods often show intense bipolar staining. Coccoid forms, usually scattered, may occur as aggregates or clumps on the red cell, apparently embedded in a faint blue matrix.

A pale blue veil-like substance may cover nearly half of one surface of the red cells and show at its border typical red-violet stained rods or filaments in the Giemsa-stained specimens. A bow-shaped arrangement of elements is characteristic. Organisms lie on the surface of the red cells. In cultures organisms are more uniform in morphology resembling *Bartonella bacilliformis*. Individual organisms are fine rods, 0.3 by 1.0 to 2 microns, sometimes occurring in chains and often in clumps. Small round forms occur, measuring 0.5 micron in diameter, and occasionally round disk-like structures.

**Cultivation.** Growth in Noguchi's semi-solid serum agar 2 weeks after inoculation with citrated or heparinized blood and incubated at 23°C shows as white rounded masses, measuring up to about 1 mm in the upper 15 mm of the tube. In tissue culture the organism grows in small, rounded compact masses within the cytoplasm of infected cells. Indefinite maintenance of the strains isolated on artificial media has not been possible.

**Pathogenicity.** Splenectomized white mice and splenectomized laboratory

reared voles are readily susceptible to infection. No marked anemia or any mortality in heavily infected animals. Splenectomized dogs, white rats and deer mice are not susceptible.

**Source and habitat.** Erythrocytes of the vole (*Microtus pennsylvanicus pennsylvanicus*) following splenectomy. The natural mode of transmission has not been determined though ticks or mites are suspected.

4 *Haemobartonella tyzzeri* (Weinman and Pinkerton) Weinman. (*Bartonella tyzzeri* Weinman and Pinkerton, Ann Trop Med, 52, 1938, 217; Weinman, Trans Amer Philosoph. Soc, 53, 1944, 314) Named for Prof Tyzzer who studied haemobartonellae.

Single or composite rods from about 0.25 micron by 1.4 to 4.0 microns. Occasional granular swellings and enlarged poles. Short rods also occur averaging 0.2 to 0.3 by 0.8 micron and also round forms with diameters of 0.2 to 0.3 micron. Distributed irregularly in the red cells. Stain intensely red-violet with Giemsa's or May-Grünwald-Giemsa's solutions. Gram-negative.

**Cultivation.** Initial cultures on Noguchi's semi-solid serum agar obtained irregularly. When incubated at 25°C, colonies appear as isolated white spheres about 1 mm in diameter in the upper 8 mm border of the medium. The clumps are composed of rods and granules, with larger round structures or disks occurring occasionally. Also cultivated on the Zinsser, Wei and Fitzpatrick modification of the Mutland medium. Prolonged maintenance on semi-solid media has not been obtained.

**Pathogenicity.** Splenectomized haemobartonella-free guinea pigs may be infected by blood or cultures injected subcutaneously or intraperitoneally. Splenectomized *Haemobartonella muris*-free rats are susceptible when inoculated with infected guinea-pig blood. *Macacus rhesus* monkeys are also in-

susceptible to inoculations of infected blood, tissue and cultures. Infection of the guinea pig is subclinical in its manifestations, probably due to the small number of parasites in the blood. No definite anemia accompanies infection.

Source and habitat: Erythrocytes of the Peruvian guinea pig (*Cavia porcellus*). Has also been encountered in Colombia but not in other parts of the world. Observed in latently infected animals only after splenectomy. The natural mode of transmission is unknown, though the flea may be a possible vector.

5. *Haemobartonella bovis* (Donatien and Lestoquard) Weinman. (Donatien and Lestoquard, Bull. Soc. Path. Exot., 27, 1934, 652; *Bartonella sergenti* Adler and Ellenbogen, Jour. Comp. Path. and Therap., 47, 1934, 221; (?) *Bartonella bovis* Rodriguez, Rev. del Inst. Llorente, 13, 1935, 5; abst. in Bull. Inst. Past., 34, 1936, 1033; Weinman, Trans. Amer. Philosoph. Soc., N. S., 33, 1944, 308; *Haemobartonella sergenti* Weinman, loc. cit., 290.) From Latin *bos*, *bovis*, ox.

Resembles *Haemobartonella muris* and *H. canis*. Occurs as rods, coccobacilli and cocci, singly, in pairs or short chains or groups of 10 or more elements. The rods measure 1.2 to 2 microns in length and are very slender. The coccobacilli occur singly or in pairs measuring 0.3 by 0.6 to 0.8 micron and the diameters of the cocci are about 0.3 micron. The parasite may occupy a central or marginal position on the red cell, the number on a cell varying from 1 to 20. Not more than 20 per cent of the cells are parasitized.

Using the Romanowsky stain, the organisms stain similarly to the chromatin of *Piroplasma* spp.

Source and habitat: In the blood of bulls in Algeria and in a non-splenectomized calf in Palestine.

6. *Haemobartonella sturmanii* Grinberg. (Grinberg, Ann. Trop. Med., 33,

1939, 33; Weinman, Trans. Amer. Philosoph. Soc., N. S., 33, 1944, 313.)

Similar to *Haemobartonella bovis* and *H. canis* in morphology and staining properties. Occurs as rods, coccobacillary and coccoid forms, varying in length from 0.5 to 1.5 microns. The number of parasites per infected cell varies from 1 to 15 and they occur individually, scattered irregularly in clumps or sometimes in chains stretching across the cell. At the height of the infection more than 90 per cent of the cells are infected.

Pathogenicity: Causes a temperature rise in buffaloes and slight anemia after direct blood inoculation. Splenectomized rabbits, hamsters and splenectomized calves inoculated with blood from infected buffaloes remained free of the parasite.

Source and habitat: In the blood of buffaloes in Palestine.

7. *Haemobartonella peromyscii* Tyzzer. (Proc. Amer. Philos. Soc., 85, 1942, 377.) Named for the genus of deer mice, *Peromyscus*.

Occurs as delicate filamentous forms (which may be branched) on the red blood cells. These filaments may become beaded and give rise to a number of coccoids and rods from which ring forms may develop.

Stains by Giemsa's method, but staining process must be intense in order to demonstrate the organism.

Pathogenicity: Infection transmissible to splenectomized white rats, white mice and voles, producing a more or less severe illness with anemia.

Habitat: In the blood of the deer mouse (*Peromyscus leucopus norboracensis*).

7a. *Haemobartonella peromyscii* var. *maniculati* Tyzzer. (Proc. Amer. Philos. Soc., 85, 1942, 381.) Named for the species of mouse from which it was isolated.

Occurs as rods and filamentous

branched forms. Coarser filaments appear to rise from rounded granules. Delicate rods are preponderant, and minute coccoids appear occasionally. When transferred to the common deer mouse, coarser forms appear, including filaments and large coccoids, sometimes in chains.

**Pathogenicity:** Pathogenic for gray-backed deer mice and the common deer mouse, but non-infective for splenectomized white mice.

**Habitat:** Blood of the gray-backed deer mouse (*Peromyscus maniculatus gracilis*).

8 *Haemobartonella blarinse* Tyzzer (Proc. Amer. Philos. Soc., 85, 1942, 382)

Named for the genus of shrews, *Blarina*

Extremely pleomorphic with delicate rods and coccus-like forms, often occurring in chains which also contain larger elements which have a deeply stained, bead-like granule. In the early stages of infection they may occur as thick bands or filaments stretching over the red cells usually with a bead or granule.

The bands take a bluish tint with Giemsa's stain, while the more delicate form stains a slaty violet. The head is distinctly reddish. In the fully developed infection, rods and filaments predominate over rounded forms. The organisms may be scattered on the surface of the red cells or may form a dense cap which is intensely stained. Rudimentary mycelia may be found radiating from a central portion and reddish stained material with ill-defined contours may occur at the ends of the mycelial branches.

**Pathogenicity:** Pathogenic for the short-tailed shrew but not for deer mice or white mice. Causes anemia in the shrew.

**Habitat:** In the blood of the short-tailed shrew (*Blarina brevicauda*).

9 *Haemobartonella sciuril* Tyzzer (Proc. Amer. Philos. Soc., 55, 1912, 385)

Named for the genus of gray squirrels, *Sciurus*.

Very pleomorphic. Occurs as minute rods and filaments which are continuous or segmented. The rods and filaments vary in thickness, some are very uneven and some very coarse. Beaded chains may develop from the thickened forms.

The bead-like elements stain a dull reddish at the periphery with Giemsa's stain while the remainder is very faintly stained in contrast to the intensely staining basophilic rods and filaments. Some of the rounded forms have the appearance of large, thick rings. Beads and rings may arise from slender deeply staining rods, simulating very closely spores within bacilli, though no germination of filaments from them has been observed.

**Pathogenicity:** Slightly pathogenic for the gray squirrel, non-pathogenic for normal white mice.

**Habitat:** Blood of the gray squirrel (*Sciurus carolinensis leucotis*).

**Appendix:** Here are included (1) *Haemobartonella* of undetermined specific rank, (2) *Haemobartonella*-like structures in non-splenectomized mammals and in cold-blooded animals, (3) Invalid species (see Weinman, Trans. Amer. Philosoph. Soc., N. S., 53, 1914, 315).

1 *Haemobartonellae* of undetermined specific rank. Microorganisms are grouped according to host of origin and are considered to be *haemobartonellae* from the description of the original author; but the information furnished is not sufficient for further classification.

*Haemobartonellae* similar to *Haemobartonella muris* in wild rats: *Mus decumanus*, *Mus norvegicus*, *Rattus rattus frugivorus*, *Mus rattus griseiventris*, *Mus rattus rattus*, *Mus sylvaticus*. In various rats; technical names not given.

*Haemobartonellae* similar to *Haemobartonella muris* in albino mice. Schilling (Klin. Wchnschr., 1929, 55) separated the *haemobartonella* of the mouse from

that of the rat and named it *Bartonella muris musculi* var. *albinoi* (*Haemobartonella muris musculi* var. *albinoi* Weinman, loc. cit., 290).

*Haemobartonellae* similar to *Haemobartonella muris* in other mammals: *Haemobartonella glis glis* (Kikuth) Weinman (*Bartonella glis glis* Kikuth, Cent. f. Bakt., I Abt., 123, 1931, 356; Weinman, loc. cit., 317) in dormice (*Glis glis*).

*Haemobartonella opossum* (Regendanz and Kikuth) Weinman (*Bartonella opossum* Regendanz and Kikuth, Arch. f. Schiffs- u. Tropenhyg., 32, 1928, 587; Weinman, loc. cit., 290) in the marsupial rat (*Metachirus opossum*) and in the opossum (*Didelphys didelphys*).

*Haemobartonella* spp. in *Lophuromys ansorgei*, in *Lophuromys italicus*, in *Oenomys bacchante editus*, in *Præomys jacksoni*, in *Arvicanthus striatus*, in deer mouse (*Peromyscus leucopus novaboracensis*), in Chinese hamsters (*Cricetulus griseus*, *Cricetulus griseus fumatus*), in *Apodemus agrarius* and *Phodopus praedilectus*, and in squirrels (*Sciurus vulgaris*). Mixed infections, including *haemobartonellae* are found in gerbils, the gerbille and various rodents (see Weinman, loc. cit., 317-319).

## 2 *Haemobartonella*-like structures in non-splenectomized mammals and cold-blooded animals

Various bodies whose proper classification in the genus *Haemobartonella* has not been established (Weinman, loc. cit., 319)

In non-splenectomized mammals:

*Bartonella melloi* Yakimoff and Rastegaieff, Bull. Soc. Path. Exot., 24, 1931, 471 (*Haemobartonella melloi* Weinman, loc. cit., 290) in the ant eater (*Manis pentadactyla*).

*Bartonella pseudocebi* Pessoa and Prado, Rev. biol. e hyg., 1, 1927, 116 (*Haemobartonella pseudocebi* Weinman, loc. cit., 290) in the monkey (*Pseudocebus apella*).

*Bartonella rocha-limai* Faria and Pinto, Compt. rend. Soc. Biol., Paris, 95, 1926,

1500 (*Haemobartonella rocha-limai* Weinman, loc. cit., 290) in the bat (*Hesperiderma brevicauda*).

*Bartonella* sp. in the rat (*Rattus rufescens*) and *Bartonella* sp. in the dormouse (*Myoxus glis*).

In cold-blooded animals:

*Bartonella parlovskii* Epstein, A. Union. Inst. Exper. Med., Moscow, 1933, 398, see Ray and Idnani, Indian Jour. Vet. Sci. and Animal Husb. 10, 1940, 25 (*Haemobartonella parlovskii*, Weinman, loc. cit., 290) in the lamprey (*Petromyzon marinus*).

*Bartonella nicolleti* Yakimoff, Arch. Inst. Pasteur Tunis, 17, 1928, 350 (*Haemobartonella nicolleti* Weinman, loc. cit., 290) in the brochet (*Esox lucius*).

*Bartonella ranarum* da Cunha and Munez, Compt. rend. Soc. Biol., Paris, 97, 1927, 1091 (*Haemobartonella ranarum* Weinman, loc. cit., 290) in the frog (*Lepidactylus ocellatus*). This is probably identical with *Bartonella batrachorum* Zavattari, Boll. d. Soc. ital. biol. sper., 6, 1931, 121 (*Haemobartonella batrachorum* Weinman, loc. cit., 290) from the same species.

*Bartonella* sp. in the gecko (*Platydictylus mauritanicus*), *Bartonella* sp. in the lizard (*Lucertilia* sp.), *Bartonella* sp. in the lizard (*Tropidurus peruvianus*), *Bartonella* sp. in the tench (*Tinca tinca*) and *Bartonella* sp. in the tortoise (*Testudo graeca*).

## 3. Invalid species:

*Bartonella caviae* Campanacci, Ateneo parmonese, 1, 1929, 99 (*Haemobartonella caviae* Weinman, loc. cit., 290) from the guinea pig.

*Bartonella ukrainica* Rybinsky, Rev. Microbiol. epidem. et parasitol., 8, 1929, 296 (*Haemobartonella ukrainica* Weinman, loc. cit., 290) from the guinea pig.

Weinman (loc. cit., 314) states that the parasitism of these structures was not proven and no illustrations are furnished by the authors.

Genus III. *Grahamella* Brumpt.

(Brumpt, Bull. Soc. Path. Exot., 4, 1911, 514, *Grahamia* Tartakowsky, Trav. IX\* Cong. Int. Med. Vet., 4, 1910, 242, not *Grahamia* Theobald, Colonial Office, Misc. Pub. No. 237, 1909) Named for G. S. Graham-Smith who discovered the parasite in the blood of voles.

Parasites occurring within the erythrocytes of the lower mammals which morphologically bear a resemblance to *Bartonella*, but which are less pleomorphic, more plump, and more suggestive of the true bacteria. They stain more deeply than bartonellae with Giemsa's stain, stain lightly with aniline dyes and with methylene blue. They are Gram-negative, non-acid-fast and non-motile. Splenectomy has no effect on the source of infection except in rats. They are non-pathogenic and not affected by arsenicals. Several species have been cultivated on cell-free media.\* The etiological agent of grahamellosis of rodents and some other vertebrates.

The type species is *Grahamella talpae* Brumpt.

1. *Grahamella talpae* Brumpt (Bull. Soc. Path. Exot., 4, 1911, 514) Named for the genus of moles, *Talpa*.

Long or short rods of irregular contour lying within the red blood cells, many with a marked curve, often near one of the extremities. One or both ends of the longer forms enlarged, giving a wedge or club shaped appearance. Some of the medium-sized forms definitely dumbbell-shaped, small forms nearly round.

With Giemsa's stain, the protoplasm of the organism stains light blue, with darker areas at the enlarged ends. Dark staining areas of longer forms give the organism a banded appearance. Length varies from 0.1 to 1 micron. Parasites occasionally free in the plasma, but usually in groups. Most of the infected corpuscles contain between 6 and 20 parasites (Graham-Smith, Jour. Hyg., 5, 1905, 453).

Pathogenicity. Pathogenic for moles.

Appendix: In addition to *Grahamella talpae* Brumpt, descriptions of the following species occur in the literature. The list may not be complete and the

validity of these species may be questioned in some cases.

*Grahamella acodon* Carini (Ann. Parasit., 2, 1921, 253) From *Acodon serrensis*, Brazil.

*Grahamella alactagae* Tartakowsky. (Katalogue der Exponaten der Landwirtschaftlichen Ausstellung (Russisch), St. Petersburg, 1913) From *Alactaga saliens* and *Alactaga aconitus* in Transcaucasia and steppes of Astrakhan (*Alactaga* misspelled *Alactoga*). Quoted from Yakimoff, Arch. f. Protistenk., 66, 1929, 303.

*Grahamella arialis* Tartakowsky. (Katalogue der Exponaten der Landwirtschaftlichen Ausstellung (Russisch), St. Petersburg, 1913) From *Microtus aralis* in Transcaucasia. Quoted from Yakimoff, Arch. f. Protistenk., 66, 1929, 304.

*Grahamella balfourii* Brumpt (*Grahamella* sp. Balfour, Rept., Wellcome Tropical Research Laboratory, 2, 1906, 97, *Grahamella balfourii* Brumpt, Bull. Soc. Path. Exot., Paris, 4, 1911, 517) From the desert rat (*Jaculus jaculus*) in the Sudan.

---

\* Tyzzer (Proc. Amer. Philos. Soc., 85, 1912, 375) finds that grahamellae isolated in culture show a close relationship to *Streptobacillus moniliformis* (*Actinomyces muris*) and proposes the inclusion of the genus *Grahamella* in the family *Actinomycetaceae*. The latter relationship appears to be very doubtful.

*Grahamella blarinae* Tyzzer. (Proc. Amer. Philos. Soc., 85, 1912, 370.) From the short-tailed shrew (*Blarina brevicauda*) in Massachusetts.

*Grahamella bovis* Marzinowsky. (Med. Obosrenie, 1917, No. 1-2.) From the ox (*Bos taurus*) in Russia. Quoted from Yakimoff, Arch. f. Protistenk., 66, 1929, 304.

*Grahamella brumpti* Ribeyro and del Aquilla. (Ann. Fac. Med., Lima, 1, 1918, 14-20.) From *Desmodus rufus* in Peru.

*Grahamella canis lupus* Kamalow. (Cent. f. Bakt., I Abt., Orig., 128, 1933, 197.) From the wolf, Tiflis.

*Grahamella couchi* Neitz. (Onderst. Jour. Vet. Sci. and An. Ind., 10, 1938, 29.) From the multimammate mouse (*Mastomys coucha*) in South Africa.

*Grahamella criceti domestici* Parzwanidze. (Das Material zum Hämo-parasitismus der Tiere bei Uns. Tiflis, 1925.) From *Cricetus domesticus* in Transcaucasia. Quoted from Yakimoff, Arch. f. Protistenk., 66, 1929, 304.

*Grahamella cricetuli* Patton and Hindle. (Proc. Roy. Soc., London, B(100), 1926, 387.) From *Cricetulus griseus* in China.

*Grahamella dachukowskyi* Tartakowsky. (*Grahamia* sp., Dschunkowsky and Luhs, Trav. IX. Cong. Internat. Med. Vet., 1909, 4, 1910, 242, *Grahamia dachukowskyi* Tartakowsky, 1910.) From the bat (*Vespertilio noctula*) in Transcaucasia. Ref. to Tartakowsky quoted from Yakimoff, Arch. f. Protistenk., 66, 1929, 304.

*Grahamella dudtschenkoi* Yakimoff (*Grahamella* sp., Dudtschenko, Cent. f. Bakt., I Abt., Orig., 74, 1914, 241; *Grahamella dudtschenkoi* Yakimoff, Arch. f. Protistenk., 66, 1929, 304.) From the hamster (*Cricetulus* sp.) in Transbaikal.

*Grahamella ehrlichi* Yakimoff. (*Grahamella ehrlichi* Yakimoff, Arch. f. Protistenk., 66, 1929, 305.) From the perch (*Perca fluviatilis*) in Russia.

*Grahamella francai* Brumpt. (*Grahamella* sp. Franca, Arch. Inst. Bacter. Camara, Pestana, 3, 1911, 277; *Grahamella francai* Brumpt, Précis de Parasitologie, 2ème éd., 1913, 102.) From the jumping rat (*Eliomys quercinus*) in Portugal.

*Grahamella gallinarum* Carpano. (Ann. Parasit. hum. et comp., 13, 1935, 238.) From leghorn chickens in Egypt.

*Grahamella gerbilli* Sassuchin. (*Grahamia gerbilli* Sassuchin, Arch. f. Protistenk., 74, 1931, 526.) From *Gerbillus tamaricinus* in southeast Russia.

*Grahamella hegneri* Sassuchin (*Grahamia hegneri* Sassuchin, Arch. f. Protistenk., 75, 1931, 152.) From *Citellus pygmaeus* in Russia.

*Grahamella joyeuxi* Brumpt. (*Grahamella* sp., Joyeux, Bull. Soc. Path. Exot., Paris, 6, 1913, 614; *Grahamella joyeuxi* Brumpt, Précis de Parasitologie, 2ème éd., 1913, 102.) From *Golunda fallax* and *Mus rattus* in French Guinea.

*Grahamella merionis* Adler. (Trans. Roy. Soc. Trop. Med., 24, 1930, 78.) From *Meriones tristrami* in Palestine.

*Grahamella microti* Lavie. (Bull. Soc. Path. Exot., Paris, 14, 1921, 573.) From *Microtus arvalis* in France.

*Grahamella microti pennsylvanicus* Tyzzer. (Proc. Amer. Philos. Soc., 85, 1912, 366.) From the common vole (*Microtus pennsylvanicus pennsylvanicus*) in Massachusetts.

*Grahamella muris* Carini. (Bull. Soc. Path. Exot., Paris, 8, 1915, 104.) From the house rat (*Mus decumanus*) in Brazil.

*Grahamella muris musculi iberica* Parzwanidze. (Das Material zum Hämo-parasitismus der Tiere bei uns Tiflis, 1925.) From *Mus musculus* in Transcaucasia. Quoted from Yakimoff, Arch. f. Protistenk., 66, 1929, 304.

*Grahamella musculi* Benoit-Bazille. (Bull. Soc. Path. Exot., Paris, 13, 1920, 408.) From *Mus musculus* var. *alpinus* in France.

*Grahamella ninae* Kohl-Yakimoff. (Bull. Soc. Path. Exot., Paris, 10,

1. *Pseudomonas aeruginosa* (Schroeter) Migula. (*Bacterium aeruginosum* Schroeter, in Cohn, Beitrage z Biologie, 1, Heft 2, 1872, 126; *Bacillus pyocyaneus* Gessard, Compt. rend. Acad. Sci., Paris, 94, 1882, 536; *Micrococcus pyocyaneus* Zopf, Spaltpilze, 2 Aufl., 1884, 83; *Bacillus aeruginosus* Trevisan, Atti Accad. Fis.-Med. Stat., Milano, Ser. 4, 3, 1885, 11; *Bacillus fluorescens* Crookshank, Man. of Bact., 3rd ed., 1890, 247; not *Bacillus fluorescens* Bergey et al., Manual, 1st ed., 1923, 287; *Pseudomonas pyocyanea* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 29, *Bacterium pyocyaneum* Lehmann and Neumann, Bakt. Diag., 1 Aufl., 2, 1896, 267; Migula, Syst. Bakt., 2, 1900, 884.) From Latin, full of copper rust, or verdigris; green

Rods: 0.5 to 0.6 by 1.5 microns, occurring singly, in pairs and short chains. Motile, possessing one to three polar flagella. Monotrichous (Reid, Naghski, Farrell and Haley, Penn. Agr. Exp. Sta., Bull. 422, 1942, 6). Gram-negative.

Gelatin colonies: Yellowish or greenish-yellow, fringed, irregular, skein-like, granular, rapidly liquefying.

Gelatin stab: Rapid liquefaction. The fluid assumes a yellowish-green or bluish-green color.

Agar colonies: Large, spreading, grayish with dark center and translucent edge, irregular. Medium greenish.

Agar slant: Abundant, thin, white, glistening, the medium turning green to dark brown or black, fluorescent.

Broth: Marked turbidity with thick pellicle and heavy sediment. Medium yellowish-green to blue, with fluorescence, later brownish. Produces pyocyanin, fluorescein and pyrorubrin (Am. Jour. Hyg., 5, 1925, 707).

Litmus milk: A soft coagulum is formed, with rapid peptonization and reduction of litmus. Reaction alkaline.

Potato: Luxuriant, dirty-brown, the medium becoming dark green.

Indole usually not formed (Sandiford, Jour. Path. and Bact., 44, 1937, 567).

Nitrates are reduced to nitrites and nitrogen.

Glucose, fructose, galactose, arabinose, maltose, lactose, sucrose, dextrin, inulin, glycerol, mannitol and dulcitol are not attacked. Acid from glucose (Sandiford, loc. cit.).

Blood serum: Liquefied. Yellow liquid, greenish on surface.

Blood hemolyzed.

Cultures have marked odor of trimethylamine.

Aerobic, facultative

Optimum temperature 37°C.

Pathogenic for rabbits, guinea pigs, rats and mice.

Common name: Blue pus organism.

Source: Pus from wounds. Regarded as identical with one of the plant pathogens (*Pseudomonas polycolor*) by Elrod and Braun (Jour. Bact., 44, 1942, 633).

Habitat: Cause of various human and animal lesions. Found in polluted water and sewage.

2. *Pseudomonas jaegeri* Migula. (*Bacillus proteus fluorescens* H. Jaeger, Ztschr. f. Hyg., 12, 1892, 593; Migula, Syst. d. Bakt., 2, 1900, 885; *Bacillus proteus-fluorescens* Holland, Jour. Bact., 5, 1920, 220; *Proteus fluorescens* Holland, *ibid.*, 224; *Pseudomonas protea-fluorescens* Holland, *ibid.*, 224.) Named for H. Jaeger who first described the species.

Short, thick rods, with rounded ends, occurring singly and in pairs. Motile with a tuft of polar flagella which may be pushed to one side where cells remain in a chain. Gram-negative.

Gelatin colonies: Small, transparent, becoming proteus-like.

Gelatin stab: Marked surface growth.

Saccate to infundibuliform liquefaction. Liquefied portion green fluorescent.

Agar slant: Thick, yellowish-white layer, the medium becoming greenish-fluorescent. At times gas is formed.

Broth: Turbid, with greenish-gray pellicle and sediment.

Litmus milk: Not coagulated.

1. *Eperythrozoon coccoides* Schilling. (Schilling, Klin. Wchnschr., 1928, 1854; *Gyromorpha musculi* Dinger, Nederl. tijdschr. geneesk., 72, 1928, 5905.) From Greek, coccus-shaped.

In stained blood films these organisms appear as rings, coccoids and rods, the majority as rings of regular outline with clear centers. They are in the plasma and on the red cells. Measure 0.5 to 1.4 microns in greatest dimension.

Stain pale red or reddish-blue with the Giemsa or the May-Grunwald-Giemsa techniques. Gram-negative.

Suggested methods of multiplication by binary fission, budding, development of small coccoidal to annular forms.

Cultivation: Negative results.

Immunology: Immunological state in animals that of the premunition type. Latent infection in mice which is made manifest by splenectomy.

Pathogenicity: Pathogenic for white mice, rabbits, white rats, wild mice, usually in young animals or in splenectomized adults.

Source: Blood of splenectomized white mice.

Habitat: Blood of infected animals, mouse louse (*Polyplox serrata*) and probably other arthropods.

2. *Eperythrozoon ovis* Neitz, Alexander and Du Toit. (Neitz et al, Address, Biological Society, Pretoria, Mar 15, 1934; from Neitz, Onderst. Jour. Vet. Sci. and An. Ind., 9, 1937, 9.) From Latin *ovis*, sheep.

Delicate rings approximately 0.5 to 1.0 micron in diameter though occasionally larger. In addition there are triangles with rounded angles, ovoid, comma, rod, dumbbell and tennis racket forms. Found supra-cellularly on the erythrocytes but often free. Colored pale purple to pinkish-purple with Giemsa's stain. Suggested mode of multiplication by budding.

Cultivation: Negative results.

Immunology: Immunological state in sheep appears to be that of the premunition type.

Pathogenicity: Sheep, antelopes and probably goats and splenectomized calves are susceptible. Dogs, rabbits and guinea pigs are refractory. The distinctive feature of *Eperythrozoon ovis* is its ability to provoke illness in normal animals without resorting to splenectomy.

Source: Blood of infected South African sheep.

Habitat: Blood of infected animals. No ectoparasites found on sheep naturally infected, but an arthropod is suspected.

3. *Eperythrozoon wenyoni* Adler and Ellenbogen. (Adler and Ellenbogen, Jour. Comp. Path. and Therap., 47, 1934 (Sept. 3), 220; see *Barlonella wenyoni* in appendix.) Named for Dr. C. M. Wenyon, a student of these organisms.

Morphologically similar to *Eperythrozoon coccoides*. Coccoid and often vesicular, staining pale red with Giemsa's stain and varying from 0.2 to 1.5 microns in diameter. Multiplication seems to be by budding and fission, and by filamentous growths from the ring forms, suggesting resemblance to *Hyphomycetes*. Up to 50 or 60 parasites are found on one cell. These are arranged in irregular chains or in tightly packed groups.

Cultivation not reported.

Immunology. The organism creates a state of premunition and latent infection is made manifest by splenectomy.

Pathogenicity: Cattle are susceptible, but sheep are not infected either before or after splenectomy.

Source: Blood of infected cattle.

Habitat: Blood of infected cattle, arthropod transmission not proven.

4. *Eperythrozoon varians* Tyzzer. (Proc Amer Philos. Soc., 85, 1942, 337.) From Latin *varians*, varying.

1917, 99.) From the hamster (*Cricetus phoca*) in Transcaucasia.

*Grahamella peromysci* Tyzzer (Proc. Amer. Philos. Soc., 85, 1912, 363) From the deer mouse (*P. leucopus notaboracensis*) in Massachusetts

*Grahamella peromysci* var. *maniculati* Tyzzer (Proc. Amer. Philos. Soc., 85, 1912, 365) From the gray-backed deer mouse (*Peromyscus maniculatus*) in Massachusetts.

*Grahamella phyllotidis* Tyzzer (Proc. Amer. Philos. Soc., 85, 1912, 371) From the Peruvian mouse (*Phyllotis darwini linatus*).

*Grahamella pipistrelli* Markow. (*Grahamia pipistrelli* Markow, Russian Jour. Trop. Med., 1926, No. 5, 52) From the bat (*Pipistrellus nathussii*) in Russia.

*Grahamella rhesi* Leger. (Bull. Soc. Path. Exot., Paris, 15, 1922, 680.) From the monkey (*Macacus rhesus*) in Annam.

*Grahamella sanis* Cerruti. (Arch. Ital. Sci. Med. Col., 11, 1930, 522) From *Testudo graeca* in Sardinia

*Grahamella talassochelys* Cerruti. (Arch. Ital. Sci. Med. Col., 12, 1931, 321) From *Talassochelys caretta* in Sardinia. (Misspelled for *Thalassochelys*.)

#### Genus IV. *Eperythrozoon* Schilling.\*

(Schilling, Klin. Wchnschr., 1928, 1854, *Gyromorpha* Dinger, Nederl. tijdschr. geneesk., 72, 1928, 5903) From Greek meaning animal on red blood cell

Microscopic blood parasites found in the plasma and on the erythrocytes. They stain well with Romanowsky type dyes, and then appear as rings, coccoids or short rods, 1 to 2 microns in greatest dimension, staining bluish or pinkish violet. They show no differentiation of nucleus and cytoplasm. The organisms are not known to retain the violet in Gram's method or to be acid-alcohol-fast. Splenectomy activates latent infection. Not cultivated in cell-free media. Arthropod transmission has been established for one species (Weinman, Trans. Amer. Philosoph. Soc., N.S. 33, pt. 3, 1914, 321)

The type species is *Eperythrozoon coccoides* Schilling.

#### Key to the species of genus *Eperythrozoon*.

- I. Etiological agent of eperythrozoonosis of white mice
  - 1 *Eperythrozoon coccoides*.
- II. Etiological agent of eperythrozoonosis of sheep.
  2. *Eperythrozoon oris*.
- III. Etiological agent of eperythrozoonosis of cattle
  - 3 *Eperythrozoon uenyonis*.
- IV. Etiological agent of eperythrozoonosis of gray-backed deer mice
  - 4 *Eperythrozoon varians*.
- V. Etiological agent of eperythrozoonosis of voles and dwarf mice
  - 5 *Eperythrozoon dispar*.

---

\* This genus has been considered as belonging to the Protozoa by Neitz, Alexander and Du Toit (Onderst. J. Vet. Sci., 5, 1931, 268) and to the bacteria by Meunil (Bull. Soc. Path. exot., 22, 1929, 531) and by Tyzzer (in Weinman, Trans. Amer. Philosoph. Soc., N.S., 33, pt. 3, 1914, 241) The evidence at hand favors the inclusion of this group among those organisms which are not protozoan in nature but which are closely related to bacteria.

## FAMILY III. CHLAMYDOZOACEAE MOSHKOVSKY.\*

(Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), 19, 1945, 12.)

Small, pleomorphic, often coccoid microorganisms usually with characteristic development cycle. Stain with aniline dyes. Gram-negative. Behave as obligate intracytoplasmic parasites. Have not been cultivated in cell-free media. Criteria adequate for classification lacking for more recently isolated members. The attribution of Genus III, *Colesiota*, either to *Rickettsiaceae* or to *Chlamydozoaceae* is still in doubt.

## Key to the genera of family Chlamydozoaceae.

## I. Cells coccoid and with life cycle.

## A. Non-cultivable in chicken embryonic tissues.

Genus I. *Chlamydozoon*, p. 1114.

## B. Cultivable in chicken embryonic tissues.

Genus II. *Miyagawanella*, p. 1115.

## II. Cells pleomorphic.

Genus III. *Colesiota*, p. 1119.

Genus I. *Chlamydozoon* Halberstaedter and von Prowazek.

(Arb. n. d. kaiserl. Gesundheitsamte, 26, 1907, 44.) From Greek *chlamydos*, cloak and *zoon*, animal.

Coccoid spherical cells with developmental cycle. Gram-negative. Intracytoplasmic habitat. Non-cultivable in chicken embryonic tissues. Susceptible to sulfonamide and penicillin action.

The type species is *Chlamydozoon trachomatis* Foley and Parrot.

1. *Chlamydozoon trachomatis* Foley and Parrot. (*Rickettsia trachomae* Busacca, Arch. Ophthalm., 52, 1935, 567; Foley and Parrot, Arch. Inst. Past. d'Algérie, 15, 1937, 339; *Rickettsia trachomatis* Foley and Parrot, *idem.*) Named for the disease, trachoma.

Coccoid bodies: Small microorganisms 200 to 350 millimicrons in diameter form the elementary bodies. Initial bodies up to 800 millimicrons in diameter and plaques up to 10 microns also found. All larger forms encapsulated with substance derived either from the agent or from the cytoplasm of the parasitized cells. Elementary body is the basic unit. Paired forms or clusters occur. Gram-negative. Stains poorly with aniline

dyes; blue or reddish-blue with the Giemsa stain and red or blue, depending on the metabolic state, with the Macchiavello stain. Matrix of plaques gives a strong reaction for glycogen. Non-motile.

Cultivation: Has never been cultivated.

Immunological aspects: Has one or more antigens in common with or closely resembling one or more present in *Miyagawanella* spp. Produces, in low concentrations, antibodies which fix complement with antigen from *Miyagawanella lymphogranulomatis*.

Pathogenicity: Pathogenic for man, apes and monkeys where it affects only

\* Prepared by Dr. Geoffrey Rake, The Squibb Institute for Medical Research, New Brunswick, New Jersey, September, 1946.

Occur in rings, coccoids of varying size, some very minute, bacillary forms

Many of the bacilli-form elements show an unstained lens-like swelling, indicating the formation of a ring within the substance of the rod. At the height of the infection most of the organisms are found in the plasma. Whenever an organism comes in contact with a red cell, it stains intensely

Pathogenesis. Pathogenic for the gray-backed deer mouse (causing anemia) and for the splenectomized common deer mouse. Not pathogenic for splenectomized white mice

Habitat: Blood of the gray-backed deer mouse (*Peromyscus maniculatus gracilis*).

5. *Eperythrozoon dispar* Bruynoghe and Vassiliadis (Ann. de Parasitol., 7, 1929, 353)

Resembles *Eperythrozoon coccoides* in staining, distribution on the erythrocytes and also in appearance except that circular disks with solid staining centers may greatly outnumber the ring forms. Found on the red blood cells and in the plasma. Size range that of *Eperythrozoon coccoides*, also some larger ring forms

Cultivation: Not successful.

Immunology. Infection is followed by premunition and latent infection is made manifest by splenectomy. Splenectomized rabbits premunized against *E. coccoides* do not react to inoculation with *E. dispar*, if the latter is injected first, they do not react to *E. coccoides*

Infectivity. Infective for the European vole (*Arvicola* [*Microtus*] *arvalis*), the American vole (*Microtus pennsylvanicus pennsylvanicus*), the dwarf mouse (*Mus minutus*), the rabbit, and *Mus acomys*

Not infective for albino rats or albino mice.

Source: Blood of infected animals.

Appendix: 1) Species incompletely studied, *Eperythrozoon* spp. and *Eperythrozoon*-like structures (Weinman, Trans. Amer. Philosoph. Soc., N. S. 33, pt. 3, 1944, 320).

*Eperythrozoon noguchii* Lwoff and Vauzel. (Bull. Soc. path. exot., 28, 1933, 397) Probably not a valid species.

*Eperythrozoon perchropovi* Yakimoff. (Arch. f. Protistenk., 73, 1931, 271.) Classification in genus *Eperythrozoon* questionable.

*Bartonella wenyoni* Nieschulz. (Ztschr. f. Infektionskr., 53, 1933, 178.) Probably identical with *Eperythrozoon wenyoni*. If valid, *Haemobartonella wenyoni*.

Possible human infection (Schöffner, Nederl. tijdschr. v. geneesk., 73, 1930, 3778).

2) Animals infected with parasites which are definitely *eperythrozoon*-like but of uncertain specificity or which are *eperythrozoon*-like in some features but which can not be definitely classified generically.

*Jerdos* sp. Kikuth. (Cent. f. Bakt., 1 Abt., Orig., 123, 1931, 356.)

*Arvicola arvalis* Zuelzer. (Zuelzer, Cent. f. Bakt., 1 Abt., Orig., 102, 1927, 419, Kikuth, Ergebn. Hyg. Bakt., Immunitätsforsch. u. Exper. therap., 13, 1932, 559.)

*Rattus rattus* Schwet. (Ann. Soc. belg. de med. trop., 14, 1931, 277)

*Sciurus vulgaris* Nauck. (Arch. f. Schiffs- u. Trop.-Hyg., 31, 1927, 322.)

*Leptodactylus pentadactylus* Carini. (Compt. rend. Soc. Biol., Paris, 103, 1930, 1312.)

1. *Miyagawanella lymphogranulomatosa* Brumpt. (Brumpt, Ann. de Parasit., 10, 1938, 153; *Ehrlichia lymphogranulomatosa* Mauro, (Reference not found.) Named for the disease, lymphogranuloma.

**Coccoid bodies:** Small microorganisms 200 to 350 millimicrons in diameter form the elementary bodies. Initial bodies up to 1 micron and plaques up to 10 microns also found. All larger forms encapsulated with a substance derived either from the agent or from the cytoplasm of parasitized cells. Elementary body is the basic unit. Paired forms or clusters occur. Gram-negative. Stain with aniline dyes, purple with the Giemsa stain and red or blue, depending on metabolic state, with the Macchiavello stain. Matrix of the plaque does not give the reaction for glycogen. Non-motile.

**Filterability.** Passes through Chamberland L<sub>2</sub> and L<sub>3</sub>, Berkefeld V and N and sometimes through Seitz EK filters.

**Cultivation:** In plasma tissue cultures of mammalian cells, in mammalian cells on agar, in the chorio-allantoic membrane or particularly in the yolk sac of the chicken embryo but has not been cultivated in the allantoic sac. Optimum temperature 37°C in tissue cultures, 35°C in the chicken embryo.

**Immunological aspects.** Has one or more antigens in common with or closely resembling one or more present in the chlamydozoa and other *miyagawanellae*. Antisera against any of these two genera react with antigens from *Miyagawanella lymphogranulomatosa* or the other *miyagawanellae* thus far tested. One common antigen has been isolated as a soluble fraction distinct from the bodies of the agent. Distinguished sharply from the other *miyagawanellae* by antitoxic neutralization of toxic factor or by neutralization of infections in mice with chicken antisera. Evidence exists that these

two serological reactions are with distinct specific antigens. Immunity in man or animals is probably poor in the absence of continuing apparent or inapparent infection.

**Toxic factor:** Infected yolk sac or yolk injected intravenously or intraperitoneally is rapidly fatal to mice. Produces characteristic lesions on the skin of normal guinea pigs.

**Pathogenicity:** Pathogenic for man, apes, monkeys, guinea pigs, cotton rats, hamsters, mice, chicken embryos. Inapparent infections may occur with the agent harbored in the organs. Causes local genital lesions, septicemia, lymphadenitis, meningitis, ophthalmitis and rarely pneumonitis in man.

**Tissue tropisms:** In laboratory rodents this species is infective by the intranasal (pneumonitis), the intracerebral (meningitis) and the intradermal routes.

**Chemotherapy:** Susceptible to relatively high concentrations of penicillin, to the sulfonamides and to some antimony compounds.

**Source:** Most commonly the genital secretions of infected individual or the draining lymph nodes. Also occasionally in blood, spinal fluid and ocular secretions.

**Habitat:** The etiologic agent of lymphogranuloma venereum, lymphogranuloma inguinale, climatic bubo, esthiomene and some forms of anorectal inflammation.

2. *Miyagawanella psittaci* (Lillie) Moshkovsky. (*Rickettsia psittaci* Lillie, Publ. Health Repts., 45, 1930, 773; *Microbacterium multiforme psittacosis* Levinthal,\* 1st Cong. internat. de Microbiol., 1, 1930, 523; Moshkovsky, Uspekhi Souremennoi Biologii (Russian) (Advances in Modern Biology), 19, 1945, 12; *Ehrlichia psittaci* Moshkovsky, *ibid.*, 19.) From *Psittaci*, an order of birds.

\* This is the type species of the genus *Microbacterium* Levinthal which is invalid because of the earlier *Microbacterium* Orla-Jensen, 1919, see p. 370.

the cornea and conjunctiva causing highly destructive lesions.

Chemotherapy: Susceptible to sulfonamides and penicillin.

Source: Found in scrapings of cornea or conjunctiva in cases of trachoma.

Habitat: The etiological agent of trachoma in man.

2. *Chlamydozoon oculogenitale* Moshkovsky. (Moshkovsky, Uspekhi Sour-emennoi Biologii, 19, 1945, 12) From Latin *oculus*, eye and *genitalis*, genital.

Morphology and staining reactions: As for *Chlamydozoon trachomatis*.

Cultivation: Has never been cultivated.

Immunological aspects: As for *C. trachomatis*.

Pathogenicity: Pathogenic for man, baboons and monkeys. Causes an acute conjunctivitis and, in man, an inflammation of the lower genito-urinary tract.

Chemotherapy: Susceptible to sulfonamides and penicillin.

Source: Found in conjunctival exudates, and in exudates from infected urethra or cervix. Also present in contaminated pools of water.

Habitat: The etiological agent of swimming pool conjunctivitis, neonatal conjunctivitis or inclusion conjunctivitis.

## Genus II *Miyagawanella* Brumpt

(Ann. de Parasit., 16, 1938, 153.) Named for Prof. Miyagawa, the Japanese bacteriologist, who first (1935) grew the type species in the chick embryo.

Coccoid to spherical cells with a developmental cycle. Gram-negative. Intracytoplasmic habitat. Cultivable in chicken embryonic tissues. Some species are susceptible to sulfonamide or penicillin action.

The type species is *Miyagawanella lymphogranulomatis* Brumpt

### Key to the species of genus *Miyagawanella*.

- I The etiological agent of lymphogranuloma venereum, lymphogranuloma inguinale, climatic bubo, and esthiomene in man
  1. *Miyagawanella lymphogranulomatis*.
- II. The etiological agent of psittacosis or parrot fever.
  2. *Miyagawanella psittaci*.
- III. The etiological agent of ornithosis (Meyer).
  3. *Miyagawanella ornithosis*.
- IV. The etiological agent of one type of viral pneumonia.
  4. *Miyagawanella pneumoniae*.
- V. The etiological agent of mouse pneumonitis (Gönnert)
  5. *Miyagawanella bronchopneumoniae*.
- VI. The etiological agent of feline pneumonitis (Baker).
  6. *Miyagawanella felis*.
- VII. The etiological agent of Louisiana pneumonia
  7. *Miyagawanella louisianae*.
- VIII. The etiological agent called the Illinois virus, the cause of one type of viral pneumonia.
  8. *Miyagawanella illini*.

4. *Miyagawanella pneumoniae* Rake, *spec. nov.* Named for the disease, pneumonia.

Coccoid bodies: As for *Miyagawanella lymphogranulomatis* but slightly smaller, circa 200 millimicrons in diameter.

Cultivation: As for *Miyagawanella psittaci*.

Immunological aspects: As for *Miyagawanella psittaci*. Distinct from *Miyagawanella ornithosis* by the neutralization test with chicken antisera.

Pathogenicity: Pathogenic for birds, man, cotton rats, hamsters, white rats, kangaroo rats, mice and chicken embryos. Causes a fatal pneumonitis in man.

Tissue tropisms: As for *Miyagawanella ornithosis*.

Chemotherapy: As for *Miyagawanella ornithosis*.

Source: Occurs in lungs of infected humans. Possibly originally of avian origin.

Habitat: The etiologic agent of one type of viral pneumonia. The type strain is the so-called strain S-F (Eaton, Beck and Pearson, *Journ. Exp. Med.*, 73, 1941, 641).

5. *Miyagawanella bronchopneumoniae* Moshkovsky (Moshkovsky, *Uspekhi Souremennoi Biologii*, 19, 1945, 19, *Ehrlichia bronchopneumoniae* Moshkovsky, *idem*) Named for the disease, bronchopneumonia.

Coccoid bodies: As for *Miyagawanella pneumoniae*.

Cultivation: As for *Miyagawanella lymphogranulomatis*. Does not grow in the allantoic cavity of the chick.

Immunological aspects: As for *Miyagawanella lymphogranulomatis* but no soluble antigen has been demonstrated.

Toxic factor: Heavily infected yolk sacs and yolk injected intravenously are very rapidly fatal to mice.

Pathogenicity: Pathogenic for mice, hamsters and ferrets. Produces a moderate, severe pneumonitis.

Tissue tropisms: Shows a predilection for the lungs.

In mice, it is also infective by the intravenous route.

Chemotherapy: Susceptible to sulfonamides and to relatively large doses of penicillin.

Source: Found in lungs of certain stocks of the laboratory mouse.

Habitat: The agent of mouse pneumonitis. Bronchopneumoniae virus (Gönnert, *Cent. f. Bakt.*, I Abt., Orig., 147, 1941, 151).

6. *Miyagawanella felis* Rake, *spec. nov.* From Latin *felis*, cat.

Coccoid bodies: As for *Miyagawanella lymphogranulomatis*.

Cultivation: As for *Miyagawanella psittaci*.

Immunological aspects: As for *Miyagawanella psittaci* but nothing known about inapparent infections in the natural host, the domestic cat.

Toxic factor: Infected yolk sac or other membranes and yolk or other fluids, injected intravenously into mice or chicken embryos or intraperitoneally into mice are rapidly fatal.

Pathogenicity: Pathogenic for cats, hamsters, mice and chicken embryos. Causes a fatal pneumonitis with acute conjunctivitis in cats.

Tissue tropisms: Predilection for lungs and conjunctivae. In laboratory rodents, this species is infective by the intranasal, intraperitoneal, intracerebral and intravenous routes.

Chemotherapy: As for *Miyagawanella ornithosis*.

Source: Lungs of infected cats.

Habitat: The etiologic agent of one form of cat nasal catarrh, influenza or distemper (Baker, *Science*, 96, 1942, 475) and feline pneumonitis.

7. *Miyagawanella louisianae* Rake, *spec. nov.* Named for the State of Louisiana.

Coccoid bodies: As for *Miyagawanella psittaci*.

Coccoid bodies: As for *Miyagawanella lymphogranulomatis*.

Filterability: Partly filterable through Berkefeld N, Chamberland L and Q or Seitz EK filters.

Cultivation: As for *Miyagawanella lymphogranulomatis* but grows readily in allantoic sac without adaptation.

Immunological aspects: As for *M lymphogranulomatis* but no soluble fraction yet demonstrated.

Toxic factor. Infected yolk sac or yolk injected intravenously or intraperitoneally is rapidly fatal to mice.

Pathogenicity Pathogenic for birds (particularly psittacine and finch species), man, monkeys, guinea pigs, pocket gophers, hamsters, white rats, kangaroo rats, mice, rabbits and chicken embryos. Inapparent infections may occur with the agent harbored in the organs. Causes a highly fatal pneumonitis with septicemia in man.

Tissue tropisms: Causes a septicemia. In man this species shows predilection for the respiratory tract. In laboratory rodents, it is infective by the intranasal, the intraperitoneal (peritonitis and septicemia), the intracerebral and the intravenous routes.

Chemotherapy Susceptible to relatively high concentrations of penicillin. Some strains are susceptible to sulfonamides.

Source: Found in the organs and nasal secretions of infected birds and, from the latter, spreads to the plumage by preening and other methods. Plentiful in droppings or dust from infected cages. Relatively resistant under such conditions.

Habitat: The etiological agent of psittacosis or parrot fever. Also of some cases of atypical pneumonia.

3. *Miyagawanella ornithosis* Rake, spec. nov. From Greek *ornithos*, bird.

Coccoid bodies: As for *Miyagawanella lymphogranulomatis*.

Cultivation: As for *Miyagawanella psittaci*.

Immunological aspects: Has one or more antigens in common with, or closely resembling, one or more present in chlamydozoa and other *myagawanellae* as shown by a cross reaction in complement fixation tests. Sharply distinguished from other *myagawanellae* by toxin-antitoxin neutralization or by neutralization of infection in mice with chicken antisera. The latter test however suggests that the agent of meningopneumonitis (Francis and Magill, Jour. Exp. Med., 68, 1938, 147) is this species rather than something distinct. Immunity in man or animals is probably poor except in the presence of continuing apparent or inapparent infections. Cross reactions suggest that *Miyagawanella ornithosis* may be more closely related to *Miyagawanella lymphogranulomatis* than is *M. psittaci*.

Toxic factor As for *Miyagawanella psittaci*.

Pathogenicity Pathogenic for birds (especially non-psittacine species), man, ferrets, guinea pigs, hamsters, white rats, kangaroo rats, mice, rabbits and chicken embryos. Inapparent infections may occur. Causes a moderately severe pneumonitis with septicemia in man.

Tissue tropisms. Causes a septicemia. In birds and man shows a predilection for the lungs. In laboratory rodents, this species is infective by the intranasal, intracerebral, intravenous and (with relatively large inocula of most strains) intraperitoneal routes.

Chemotherapy Susceptible to relatively large doses of penicillin. Not susceptible to sulfonamides.

Source: Found in organs and nasal secretions of finches, pigeons (including domestic chickens), domesticated doves, fulmar petrels and other birds. Spreads from the secretions to plumage and droppings.

Habitat: The etiological agent of ornithosis (Meyer) and meningopneumonitis (Francis and Magill).

**Habitat:** Found in scrapings of cornea or conjunctiva or in discharges from affected eyes. Etiological agent of infectious or specific ophthalmia in sheep, cattle and goats.

2. *Colesiota conjunctivae-gallii* (Coles) Rake, *comb. nov.* (*Rickettsia conjunctivae-galli* Coles, *Onders. Jour. Vet. Sci. and Indust.*, 14, 1940, 469.) From conjunctiva and Latin *gallus*, hen.

**Pleomorphic bodies:** Similar to *Colesiota conjunctivae*. Stain purplish-red or blue with the Giemsa stain.

**Cultivation:** Has never been cultivated.

**Immunological aspects:** Unknown.

**Pathogenicity:** Pathogenic for the domestic fowl. Causes an acute conjunctivitis and keratitis.

**Tissue tropisms:** As for *Colesiota conjunctivae*.

**Source:** As for *Colesiota conjunctivae*.

**Habitat:** The etiological agent of one form of ocular roup in fowls.

**Appendix:** The following are similar to or identical with the above:

*Rickettsia conjunctivae-bovis* (Coles, *South Afr. Vet. Med. Assoc.*, 7, 1936, 1) cannot be distinguished from *Colesiota conjunctivae* by any described characteristics.

*Rickettsia lestoquardi* Donatien and Gayot. (*Bull. Soc. Path. Exot.*, 35, 1942, 325.) Found in benign conjunctivitis in swine similar to that which occurs in ruminants.

**Filterability:** Filters through Berkefeld N and Mandler 6, 7 and 9 filters.

**Cultivation:** In the yolk sac of the chicken embryo.

**Immunological aspects:** Indistinguishable from other *Miyagawanella* by complement fixation tests with yolk sac antigens. Partly distinguished from *Miyagawanella psittaci* and *M. ornithosis* by active immunization in mice and guinea pigs.

**Pathogenicity:** Pathogenic for man, guinea pigs, cotton rats, mice and chicken embryos. Slightly pathogenic for white rats, golden hamsters and deer mice. *Macacus rhesus* monkeys, rabbits, muskrats and nutria are unaffected. Causes a highly fatal pneumonitis and septicemia in man.

**Tissue tropisms:** Causes a septicemia. In man this species shows predilection for the respiratory tract. In laboratory rodents it is infective by the intranasal, intraperitoneal, intracerebral, intramuscular and subcutaneous routes.

**Chemotherapy.** As for *Miyagawanella ornithosis*.

**Source:** Sputum and organs of infected persons.

**Habitat:** The etiological agent of Louisiana pneumonia (Olson and Larson, U. S. Pub. Health Repts., 59, 1944, 1373), so-called Borg strain.

8. *Miyagawanella illini* Rake, *spec. nov.* Named for the State of Illinois.

**Coccoid bodies:** As for *Miyagawanella lymphogranulomatis*.

**Filterability:** Passes through Berkefeld N or W filters.

**Cultivation:** In the yolk sac of chicken embryo.

**Immunological aspects:** Distinguished from other *Miyagawanella* by neutralization tests in mice with chicken antisera and partly from *Miyagawanella psittaci*, *M. ornithosis* and *M. pneumonia* by active immunization in mice.

**Pathogenicity:** Pathogenic for man and white mice. Causes a highly fatal pneumonitis in man.

**Tissue tropisms:** Infective in mice by the intranasal, intraperitoneal, intracerebral and subcutaneous routes.

**Source:** Lungs of infected persons.

**Habitat:** The etiological agent called the Illinois virus (Zichis and Shaughnessy, Science, 102, 1945, 301).

### Genus III. *Colestiota* Rake, *gen. nov.*

(*Rickettsia* Coles, 17th Rept. Direct. Vet. Serv. and An. Ind. Un. South Africa, 1931, 175.) Named for Prof. Coles who first studied these organisms.

**Pleomorphic cells** which may be coccoid, triangular, rod-shaped or in the form of rings. Gram-negative. Intracytoplasmic habitat.

The type species is *Colestiota conjunctivae* (Coles) Rake.

1. *Colestiota conjunctivae* (Coles) Rake, *comb. nov.* (*Rickettsia conjunctivae* Coles, 17th Rept. Direct. Vet. Serv. and An. Ind. Un. South Africa, 1931, 175; *Chlamydozoon conjunctivae* Moshkovsky, Uspekhi Soudremnoi Biologii, 19, 1945, 19.) From *M. L. conjunctiva*, the conjunctiva.

**Pleomorphic bodies:** Average diameter 600 to 950 millimicrons. May be solid and coccoid, rod shaped, or triangular, or in form of open rings or horse-shoes.

No chains. Masses frequent. No capsule. Stains with ordinary aniline dyes but less intensely than bacteria. Gram-negative. Non motile.

**Cultivation:** Has never been cultivated.

**Immunological aspects:** Unknown.

**Pathogenicity:** Pathogenic for sheep, cattle and goats. Causes acute conjunctivitis and keratitis.

**Tissue tropisms:** Affects only the conjunctiva and cornea.

Potato: Thick, pale yellow becoming dark brown layer, slimy. The medium becomes bluish-gray.

Indole not formed.

Nitrites not produced from nitrates

Aerobic, facultative

Optimum temperature 37°C.

Pathogenic for mice.

Source: Regarded by Jaeger as the cause of Weil's disease (infectious jaundice) as it was found repeatedly in patients suffering from this disease. See *Leptospira icterohaemorrhagiae*

Habitat: Water.

### 3. *Pseudomonas fluorescens* Migula.

(*Bacillus fluorescens liquefaciens* Flugge, Die Mikroorganismen, 1886, 239, Migula, in Engler and Prantl, Die natürl. Pflanzenfamilien, 1, 1a, 1895, 29; *Bacterium fluorescens* Lehmann and Neumann, Bakt. Diag., 1 Aufl., 2, 1896, 272) From Latin, *fluor*, flowing; *M. L. fluoresco*, to fluoresce

Rods: 0.3 to 0.5 by 1.0 to 1.8 microns, occurring singly and in pairs. Motile, possessing a polar flagellum. Gram-negative.

Gelatin colonies: Circular, with greenish center, lobular, liquefying quickly.

Gelatin stab: Infundibuliform liquefaction, with whitish to reddish-gray sediment.

Agar slant: Abundant, reddish layer, becoming reddish-gray. The medium shows greenish to olive-brown coloration.

Broth: Turbid, flocculent, with yellowish green pellicle and grayish sediment.

Litmus milk: No coagulation; becoming alkaline.

Potato: Thick, grayish-yellow, spreading, becoming light sepia-brown in color.

Indole is not formed

Nitrates reduced to nitrites and ammonia.

Acid from glucose

Blood serum liquefied.

Aerobic

Optimum temperature 20° to 25°C.

Not pathogenic.

Source: Water, sewage, feces

Habitat: Soil and water.

4. *Pseudomonas viscosa* (Frankland and Frankland) Migula. (*Bacillus viscosus* G. and P. Frankland, Ztschr. f. Hyg., 6, 1889, 391; Migula, Syst. d. Bakt., 2, 1900, 900.) From *M. L. viscidus*, sticky, viscid.

Small rods: 0.5 by 1.5 to 2.0 microns, occurring singly. Motile and presumably polar flagellate. Gram-negative.

Gelatin colonies: Grayish, granular, with fimbriate margin. Medium assumes a green fluorescent color around each colony.

Gelatin stab: Infundibuliform liquefaction. Liquefied portion green fluorescent with greenish-white pellicle.

Agar slant: Thin, greenish-white, the medium becoming greenish.

Broth: Turbid, with greenish pellicle.

Litmus milk: Not coagulated.

Potato: Moist, chocolate-brown, viscid.

Indole not formed.

Nitrites not produced from nitrates. Destroys nitrate with the production of ammonia.

Aerobic, facultative.

Distinctive characters: Resembles *Pseudomonas fluorescens* except that growth on agar, gelatin and potato is viscid.

Optimum temperature 20°C.

Source: Unfiltered water from Kent, England. Common

Habitat: Water.

5 *Pseudomonas fairmountensis* (Wright) Chester. (*Bacillus fairmountensis* Wright, Memoirs Nat. Acad. Sci., 7, 1895, 458; Chester, Man. Determ. Bact., 1901, 311; *Achromobacter fairmountense* Bergey et al., Manual, 1st ed., 1923, 146.) From *M. L. of Fairmount Park* (Philadelphia.)

Medium-sized rods, occurring singly, in pairs and in chains. Motile, possessing polar flagella. Gram-negative.

Gelatin colonies: Circular, white, translucent. Dark centers with a greenish shimmer, thinner edges and faint radial lines.

Gelatin stab: Crateriform liquefaction.

\* Appendix to Order Rickettsiales: The following are described species of intracytoplasmic and intranuclear parasites of Protozoa whose relationships to similar parasites of arthropods and vertebrates are not yet clear. All of the protozoan intracellular parasites are of larger size than typical members of *Rickettsiales* and some have been placed in genera (*Gladothrix*, *Micrococcus*) where the typical species do not live intracellularly.

*Genus A Caryococcus Dangeard.*

(Compt rend. Acad. Sci., Paris, 134, 1902, 1365.)

Genus established for a bacterial parasite of the nucleus of *Euglena*; organisms rounded.

The type species is *Caryococcus hypertrophicus* Dangeard.

1. *Caryococcus hypertrophicus* Dangeard. (Compt rend Acad. Sci., Paris, 134, 1902, 1365.) Parasitic in the nucleus of a flagellate (*Euglena deses*).

Occurs in the nucleus as an agglomeration of close-set, rounded corpuscles. The nucleus increases considerably in volume, the chromatin is reduced to thin layers against the membrane, the interior of the nucleus is divided into irregular compartments by chromatic trabeculae.

2 *Caryococcus cretus* Kirby (Univ. Calif Publ. Zool., 42, 1944, 210) Parasitic in the nucleus of a flagellate (*Trichonympha corbula*) from the intestine of a termite (*Procrystotermes* sp.), Madagascar

Spherules 1 to 1.5 microns or more in diameter, in preparations appearing clear with usually a chromatic, sharply defined, crescentic structure peripherally or interiorly situated, sometimes with two such bodies or several chromatic granules, parasitic in nucleus; parasitized nucleus enlarged only moderately or not at all, chromatin altered but not greatly diminished in amount.

3 *Caryococcus dilatator* Kirby (Univ Calif Publ Zool., 42, 1944, 238) Parasitic in the nucleus of flagellates (*Trichonympha chactoni* and other species of *Trichonympha*) from the intestine of

termites (*Glyptotermes iridipennis*), Australia, and other species

Spherules 0.5 micron or less in diameter, internally differentiated with stainable granule or stainable region peripherally situated; parasitic in nucleus and nucleolus, nucleus becomes greatly enlarged and the chromatin mostly or entirely disappears.

4. *Caryococcus invadens* Kirby. (Univ. Calif Publ Zool., 42, 1944, 235.) Parasitic in the nucleus of a flagellate (*Trichonympha peplophora*) from the intestine of a termite (*Neotermes howa*), Madagascar.

Spherules 1 to 1.5 microns in diameter, sometimes arranged in pairs, often internally differentiated with stainable central or peripheral granules or stained areas, parasitic in the nucleolus or endosome and nucleus, parasitized nucleolus becoming greatly enlarged and crossed by trabeculae, eventually consumed; nucleus becoming moderately enlarged, but chromatin not disappearing.

5 *Caryococcus nucleophagus* Kirby. (Univ Calif Publ Zool., 42, 1944, 236.) Parasitic in the nucleus of a flagellate (*Trichonympha corbula*) from the intestine of termites (*Procrystotermes* sp.), Madagascar, and three species of *Kaloterms* (s. l.) from Madagascar.

\* Prepared by Prof. Harold Kirby, Jr., University of California, Berkeley, California, October, 1946.

Spherules with a diameter of about 0.5 micron, sometimes arranged in pairs, sometimes with a thicker, crescentic, stainable area of the periphery on one side; parasitic within the nucleus, exterior or interior to the chromatin mass, which may be diminished in amount, but does not disappear, nor is the parasitized nucleus appreciably enlarged.

*Genus B. Drepanospira Petschenko.*

(Arch. f. Protistenk., 22, 1911, 252.)

Cell incurved in two spiral turns that are not abrupt, one of the ends pointed, the other a little rounded, no flagella, movement helicoid by means of all the body, no cell division, endospores formed, regular spherical colonies formed by individuals at certain stages of development.

The type species is *Drepanospira mülleri* Petschenko.

1. *Drepanospira mülleri* Petschenko. (*Mullerina parameci* Petschenko, Cent. f. Bakt., I Abt., Orig., 66, 1910, 90; Petschenko, Arch. f. Protistenk., 22, 1911, 252; see also Kirby, in Calkins and Summers, Protozoa in Biological Research, 1941, 1036) Parasitic in the cytoplasm of *Paramecium caudatum*.

Developing from a group of curved rods in the cytoplasm to a large, ellipsoidal mass almost filling the body. Nuclear portion occupying part of the cell.

The author regards this genus as belonging in the family *Spirillaceae* between *Spirosoma* and *Microspira*.

*Genus C. Holospora Haffkine.*

(Ann. Inst. Past., 4, 1890, 151.)

Genus established for bacterial parasites of the ciliate, *Paramecium aurelia* (= *Paramecium caudatum* ?).

The type species is *Holospora undulata* Haffkine.

1. *Holospora undulata* Haffkine (Ann. Inst. Past., Paris, 4, 1890, 151.) In the micronucleus of the ciliate *Paramecium aurelia* (= *P. caudatum* ?).

Gradually tapered at ends; 1½, 2 and 2½ spiral turns; develops from a small, fusiform body which grows and divides transversely, brings about a great enlargement of the micronucleus, which becomes filled with the spirals (see *Drepanospira mülleri* Petschenko).

Vegetative stage fusiform; elongated, elliptical, nucleus-like body in some; divides equatorially, budding at one end; transformation into spore entails enlargement, clear space separating membrane at sides, spore pointed at ends.

3 *Holospora obtusa* Haffkin (Haffkine, Ann. Inst. Past., Paris, 4, 1890, 153; also see Fiverskaja, Arch. f. Protistenk., 65, 1929, 276.) In the micronucleus of the ciliate *Paramecium aurelia* (= *P. caudatum* ?).

2. *Holospora elegans* Haffkine. (Haffkine, Ann. Inst. Past., Paris, 4, 1890, 154, see also Kirby, in Calkins and Summers, Protozoa in Biological Research, New York, 1941, 1035) In the micronucleus of the ciliate, *Paramecium aurelia* (= *P. caudatum* ?).

Spores not spiralled and both ends are rounded. Reproduction by fission, also by formation of a bud at one of the extremities of the fusiform cell. Bodies with rounded ends 12 to 30 microns long; also spindle-shaped bodies with pointed

ends, 0.5 by 3 to 6 microns (Fiveiskaja, loc cit).

The following species have been placed in genera belonging in the orders *Chlamydobacteriales* and *Eubacteriales* respectively

*Cladothrix pelomyxæ* Veley (Veley, Jour. Janu. Soc., Zool., 29, 1905, 375; see also Leiner, Arch. f. Protistenk., 47, 1924, 282, Kirby, in Calkins and Summers, Protozoa in Biological Research, New York, 1941, 1025; Hollande, Bull. Biol. France Belg., 79, 1945, 49) In the cytoplasm of the rhizopod, *Pelomyxa palustris* and probably also other species of *Pelomyxa*

Rods, 1.5 to 2.2 microns or more in length, divided into several to many sections by transverse partitions, generally aggregated in proximity to the

nuclei, which may be thickly invested by close-set bacteria applied to the surface

*Micrococcus batrachorum* (sic) Yakimoff (Arch. f. Protistenk., 72, 1930, 137) In the cytoplasm of the flagellate, *Trichomonas batrachorum* from the tree toad (*Hyla arborea*). Also seen free in preparations of the intestinal contents of *Hyla*

Round, 1 to 1.5 microns in diameter, grouped generally in aggregates of irregular form, but also occur individually

NOTE. Further descriptions of bacterial and other parasites of *Protozoa* with bibliography will be found in Calkins and Summers, Protozoa in Biological Research, New York, 1941, 1009-1113 and in Kirby, Univ. of Calif. Pub. in Zoology, 44, 1946, 193-207

SUPPLEMENT NO. 2

ORDER VIRALES  
THE FILTERABLE VIRUSES

Copyright 1948 by  
Francis O. Holmes  
Princeton, N. J.

## FILTERABLE VIRUSES\*

The so-called filterable viruses, today generally called merely viruses, are still of unknown affiliations so far as relationships to established groups of microorganisms are concerned. They are treated here as members of an order, consisting of 13 families, 32 genera and 248 species.

Among viruses as we know them, there are three constituent groups that have come to be recognized, and to some extent named and classified, through the largely separate efforts of bacteriologists, animal pathologists, and plant pathologists. Taxonomic overlapping of the three groups, viruses affecting bacteria, viruses having only animal hosts, and viruses invading higher plants, can hardly be justified as yet by available evidence. Nevertheless it has been shown that a single virus may multiply both in a plant host and in an insect vector. This seems to dispose of the thought that adaptation to a plant or animal environment would necessarily preclude utilization of other sources of the materials needed for multiplication.

For the present it seems feasible to continue with the custom, tacitly accepted in the past, of classifying bacteriophages separately as one sub-group, viruses causing diseases in seed plants as a second sub-group, and those causing diseases in animals as a third sub-group. It should be recognized that this may prove to be only a temporary arrangement, necessary because we have no evidence to warrant taxonomic overlapping of the three groups and useful while we await critical investigations and possible development of a substitute plan capable of displaying natural relationships to better advantage. Eventually evidence may become available to show that some bacteriophages can infect higher plants or animals and can increase in the new environment, or that viruses known to attack animals or plants can similarly enlarge their host ranges. Or, there may be discoveries of common physical properties that would aid in formulating an interlocking classification, for which at present we lack any substantial basis.

It is of especial significance now that the three fields be unified at least by a parallel development of nomenclature. Toward this end the present section of this supplement is directed.

---

\* Supplement No. 2 has been prepared by Francis O. Holmes, The Rockefeller Institute for Medical Research, Princeton, N. J., September, 1944. In this section, authorities for the names of plant hosts are in general as given by Gray's *New Manual of Botany*, 7th edition, and Bailey's *Manual of Cultivated Plants*, 1938, in each of these standard works will be found a list of abbreviations customarily used in botany in citing authorities for binomials.

## ORDER VIRALES Breed, Murray and Hitchens,

(Jour. Bact., 47, 1944, 421.)

**Viruses** Etiological agents of disease, typically of small size and capable of passing filters that retain bacteria, increasing only in the presence of living cells, giving rise to new strains by mutation, not arising *de novo*. A considerable number of viruses have not been proved filterable; it is nevertheless customary to include these viruses with those known to be filterable, because of similarities in other attributes and in the diseases induced. Some not known to be filterable are inoculable only by special techniques, as by grafting or by use of insect vectors, and suitable methods for testing their filterability have not been developed; moreover, it is not certain that so simple a criterion as size measured in terms of filterability will prove to be an adequate indicator of the limits of the natural group. Cause diseases of bacteria, plants and animals.

*Key to the suborders of order Virales.*

## I. Infecting bacteria.

Suborder I. *Phagineae*, p. 1128.

## II. Infecting higher plants.

Suborder II. *Phytophagineae* p. 1145.

## III. Infecting animals (insects, mammals).

Suborder III. *Zoophagineae*, p. 1225.SUBORDER I. *Phagineae subordo novus*.

Viruses pathogenic in bacteria, bacteriophages. Containing at present only one family, the *Phagaceae*

## FAMILY I. PHAGACEAE HOLMES.

(Handb. Phytopath. Viruses, \* 1939, 1.)

Characters those of the suborder. There is a single genus

*Genus I Phagus Holmes*

(Loc. cit., 1.)

Characters those of the family. Generic name from Greek *phagein*, to eat.

The type species is *Phagus minimus* Holmes

**NOTE:** *Bacteriophagum* d'Herelle (Compt. rend. Soc. Biol., Paris, 81, 1918, 1161) a genus name applied in connection with early studies of bacteriophages, had as its type species *Bacteriophagum intestinale* d'Herelle, a bacteriophage that is not now identifiable or, more probably, a mixture of such unidentifiable bacteriophages, for filtrates containing it were said to be capable of killing outright a culture of bacteria (*ibid*, 1160). The genus name *Bacteriophagum* is, therefore, regarded as a *nomen dubium*, if not also a *nomen confusum*; subsequently it was abandoned by its author, for reasons that are not clear, in favor of the genus name *Protobios* d'Herelle 1924 (Immunity in natural infectious disease; page 343 of authorized English edition by George H. Smith, Baltimore, Williams & Wilkins Co., 1924, 399 pp). *Protobios protobios*

\* Holmes, F. O., Handbook of Phytopathogenic Viruses, Burgess Publishing Company, Minneapolis, Minn., 1939, 221 pp.

d'Herelle (*loc cit*, 345), presumably the type species of this genus, was not an ordinary virus but was said to be non-parasitic (i.e., free-living) in nature, was capable of reducing sulphur, and is not now identifiable. The genus name *Protobios* and the corresponding binomial *Protobios bacteriophagus* d'Herelle are therefore regarded also as *nomina dubia* and are not used here. *Bacteriophagus* Thornberry (*Phytopath.*, 31, 1911, 23) appears to represent a variant spelling of d'Herelle's earlier genus name, it was not accompanied by any indication of what recognizable single bacteriophage served as type and thus does not modify the standing of *Bacteriophagum*.

Key to the species of genus *Phagus*.

I. Dysentery-coli bacteriophages

A. Producing large plaques, 8 to 12 mm in diameter

1. Particle size small, 8 to 12 millimicrons.

1 *Phagus minimus*

2. Particle size 15 to 20 millimicrons.

2 *Phagus minor*.

B Producing moderately large plaques, 2 to 6 mm in diameter, with distinct halo.

1 Particle size 20 to 30 millimicrons

3 *Phagus parvus*.

4 *Phagus primarius*.

5. *Phagus secundarius*.

6 *Phagus dysenteriae*.

C Plaques medium size, 1 to 3 mm in diameter, with distinct halo.

1. Particle size 25 to 40 millimicrons.

7 *Phagus medius*.

8 *Phagus strictus*.

D Plaques small, 0.5 to 1.5 mm in diameter, with soft edge or narrow halo

1 Particle size 30 to 45 millimicrons.

9 *Phagus major*.

10. *Phagus coli*.

11 *Phagus artus*.

E. Plaques very small, 0.1 to 1.2 mm in diameter, with sharp edges.

1. Particle size 50 to 75 millimicrons

12 *Phagus maximus*

II Bacteriophages attacking *Agrobacterium tumefaciens* Conn, *Pseudomonas solanacearum* Smith, *Xanthomonas citri* Dowson, *Xanthomonas pruni* Dowson, *Erwinia carlotora* Holland, *Erwinia aroideae* Holland, *Bacterium stewartii* E. F. Smith.

## A. Specific for bacterial hosts named above.

- 13. *Phagus tumoris*.
- 14. *Phagus solanacearum*.
- 15. *Phagus citri*.
- 16. *Phagus pruni*.
- 17. *Phagus deformans*.
- 18. *Phagus contumax*.
- 19. *Phagus maidis*.

III. Bacteriophages attacking *Salmonella enteritidis* Castellani and Chalmers.

- 20. *Phagus enteritidis*.
- 21. *Phagus commutabilis*.
- 22. *Phagus tertius*.
- 23. *Phagus dubius*.

IV. Bacteriophage attacking *Salmonella typhosa*.

- 24. *Phagus indicens*.

V. Bacteriophages attacking *Bacillus megatherium* DeBary, *Bacillus mycoides* Flügge, and *Rhizobium leguminosarum* Frank.A. Thermal inactivation at 75° C in 10 minutes *in vitro*.

- 1. Host may be freed from bacteriophage by heating at 80° C for 10 minutes.

- 25. *Phagus testabilis*.

- 2. Host retains virus even when heated at 90° C for 10 minutes.

- 26. *Phagus indomitus*.

## B. Thermal inactivation at 60° C in 30 minutes.

- 27. *Phagus subvertens*.

## VI. Bacteriophages attacking streptococci.

- 28. *Phagus ineptus*.
- 29. *Phagus streptococci*.
- 30. *Phagus maculans*.
- 31. *Phagus lacerans*.
- 32. *Phagus tolerans*.
- 33. *Phagus michiganensis*.

## VII. Bacteriophages attacking staphylococci.

- 34. *Phagus fragilis*.
- 35. *Phagus intermedius*.
- 36. *Phagus caducus*.
- 37. *Phagus alpha*.
- 38. *Phagus beta*.

Agar slant: Grayish-white, glistening.  
 Broth: Turbid.  
 Litmus milk: Alkaline, litmus reduced  
 Potato: Raised, granular, spreading,  
 viscid.  
 Indole is formed.  
 Nitrites not produced from nitrates  
 Aerobic, facultative.  
 Optimum temperature 20° to 25°C.  
 Habitat: Water.

6. *Pseudomonas ureae* Bergey et al  
 (Culture No 3 of Rubentschick, Cent f.  
 Bakt., II Abt., 72, 1927, 101; Bergey et  
 al., Manual, 3rd ed, 1930, 173.) From  
 Greek, *urum*, urine; M. L., *urea*, urea.

Rods: 0.6 to 0.7 by 1.7 to 2.0 microns,  
 occurring singly and in pairs Motile.  
 Gram-positive.

Gelatin stab: Infundibuliform lique-  
 faction.

Agar colonies: Circular, grayish-white.  
 Agar slant: Grayish-white layer be-  
 coming greenish-fluorescent.

Broth: Turbid

Litmus milk: Peptonized

Potato: Yellowish-brown streak

Indole not formed

Nitrates reduced with gas formation  
 Ammonia formed.

Urea attacked.

Hydrogen sulfide formed

Methylene blue reduced

Aerobic, facultative

Can grow at 0° C.

Optimum temperature 20°C.

Habitat: Sewage filter beds

This species is included here through  
 an oversight. It should have been  
 placed in the Appendix to the genus  
*Pseudomonas* as the original description  
 is too incomplete to determine its real  
 nature. It is reported to be Gram-posi-  
 tive and motile, but the number and ar-  
 rangement of flagella are not given. If  
 it really is Gram-positive, the species is  
 probably peritrichous and does not be-  
 long in *Pseudomonas*.

7. *Pseudomonas pavonacea* Levine  
 and Soppeland. (Bul. No. 77, Iowa

State Agricultural College, 1926, 41.)  
 From Latin, *pavo*, peacock

Rods: 0.5 by 4.5 microns, with truncate  
 ends, occurring singly and in chains.  
 Motile Gram-negative.

Gelatin stab: Crateriform liquefaction.  
 Medium becoming brown.

Agar colonies: Circular, raised, becom-  
 ing green, amorphous, entire.

Agar slant: Greenish, smooth, glisten-  
 ing, viscid, medium becoming slightly  
 brown.

Broth: Turbid, with viscid sediment.  
 Medium turned dark brown.

Litmus milk: Slightly alkaline. Lit-  
 mus reduced. Peptonized after 10 days.

Potato: No growth.

Indole not formed.

Nitrites not produced from nitrates.  
 Starch not hydrolyzed.

Blood serum liquefied in 5 days.

No acid or gas from carbohydrate  
 media.

Aerobic, facultative.

Optimum temperature 22°C.

Source: Isolated from activated  
 sludge

8 *Pseudomonas effusa* Kellerman et  
 al. (Kellerman, McBeth, Scales and  
 Smith, Cent. f Bakt., II Abt., 39, 1913,  
 515; also Soil Science, 1, 1916, 472; *Cel-  
 lulomonas effusa* Bergey et al, Manual,  
 1st ed, 1923, 162, *Bacillus effusus* ap-  
 pears first as a synonym in Bergey et al.,  
*ibid*; later used as name of species 5th  
 ed, 1939, 616) From Latin, *effusus*, ef-  
 fuse, spread out

Rods: 0.4 by 1.7 microns. Motile  
 with one to three polar flagella. Gram-  
 negative.

Gelatin stab: Liquefaction.

Agar slant. Luxuriant, glistening,  
 moist, creamy growth Greenish fluo-  
 rescence.

Peptone starch agar slant: Abundant,  
 flat, moist rich creamy growth. Medium  
 shows greenish fluorescence

Broth: Turbid.

Litmus milk: Alkaline Coagulation  
 and digestion.

tralized by sera specific for bacteriophages S13, C13, C36, D5, D20, D13, C18, D3, S8, C21, or C16.

Immunological relationships: Member of Smooth Dysentery Resistance Group.

Other properties: Particle size, 30 to 45 millimicrons.

Literature: Burnet, Jour. Path. and Bact., 36, 1933, 307-318.

12. *Phagus maximus* H. (*loc. cit.*, 147). From Latin *maximus*, greatest, in reference to particle size.

Common names: Bacteriophage C16, C4, C15, C20, C32, C46, D4, D12, D29, D53, H, J, K, and W. L. L.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease. Small plaques, 0.1 to 1.2 mm in diameter, with sharp edges.

Serological relationships: No cross-neutralization reaction with bacteriophages S13, C13, C36, D5, D20, D13, C18, D3, S8, C21, D6, or staphylococcus bacteriophage Au2. Agglutinated and inactivated by homologous, though not by other, antisera. For agglutination an original titer of  $2 \times 10^6$  or higher is required; the reaction is visible to the unaided eye after 24 hours at 50° C and succeeds even after inactivation by heat (70 to 85° C for 30 minutes), formaldehyde, or a photodynamic dye (proflavine).

Immunological relationships: Member of Resistance Group II.

Thermal inactivation: At or below 70° to 85° C for 30 minutes.

Other properties: Particle size estimated by filtration as 50 to 75 millimicrons, by centrifuging as 79 to 90 millimicrons, from photographs as 50 to 60 millimicrons. Rapidly inactivated by 26.3 per cent urea solution. Little or no inactivation by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes. Lysis not inhibited by 1.5 per cent or weaker solutions of sodium citrate. Thermolabile

specific soluble substance formed in lysed cultures blocks phage-antiphage reaction.

Literature: Burnet, Brit. Jour. Exp. Path., 14, 1933, 93-100, 100-108, 302-308, Jour. Path. and Bact., 36, 1933, 307-318; 37, 1933, 179-184; Burnet and Lush, *ibid.*, 40, 1935, 455-469; Burnet and McKie, *ibid.*, 36, 1933, 299-306.

13. *Phagus tumoris* H. (*loc. cit.*, 150). From Latin *tumor*, a swelling, in reference to association of this bacteriophage with bacterial tumors.

Common name: *Agrobacterium tumefaciens* bacteriophage.

Host: *Agrobacterium tumefaciens* Conn, most strains.

Insusceptible species: Some strains of *Agrobacterium tumefaciens*, *Bacterium stewartii* E. F. Smith, *Erwinia atroseptica* Bergey et al., *E. carotovora* Holland, *Pseudomonas tabaci* Stapp, *Xanthomonas beticola* Burkholder, *X. campestris* Dowson, *X. citri* Dowson, *X. phaseoli* Dowson, *X. pruni* Dowson and *X. vesicatoria* Dowson.

Geographical distribution: United States, Russia.

Induced disease: Plaques 2 to 6 mm in diameter in 4 to 6 hours, edges of plaques spotted, moth-eaten in appearance until 40 hours after seeding; enlargement then stops and the edges of the plaques become smooth, double-ringed. Infection of plants by *Agrobacterium tumefaciens* is progressively inhibited by increasing amounts of bacteriophage in inoculum.

Thermal inactivation: At 95° C in 10 minutes (another report says 70° C, time not recorded).

Other properties: Resists dilution to 1:10<sup>11</sup>; storage at 5° C for over 25 months, prompt, though not gradual, drying; 1 per cent hydrogen peroxide for 72 hours; 95 per cent ethyl alcohol for 1 hour; 70 per cent ethyl alcohol for 6 hours; 24 per cent phenol for 1 hour; 1:3000 nitric acid for 1 hour; N/64 sodium hydroxide for 1 hour.

Literature: Israelsky, Cent. f. Bakt.,

39. *Phagus durabilis*.40. *Phagus liber*.

## VIII. Bacteriophages attacking vibrios.

41. *Phagus cholerae*.42. *Phagus celer*.43. *Phagus effrenus*.44. *Phagus lentus*.IX. Bacteriophages attacking *Corynebacterium diphtheriae* Lehmann and Neumann.45. *Phagus diphtheriae*.46. *Phagus futilis*.

1. *Phagus minimus* Holmes (Handb. Phytopath. Viruses, 1939, 141.) From Latin *minimus*, least, in reference to size.  
Common name. Bacteriophage S13.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease. On plate cultures that are uniformly covered with confluent colonies of host organisms, this bacteriophage produces large cleared plaques, 8 to 12 mm in diameter, with wide shelving edges.

Serological relationships. No cross-neutralization reactions with bacteriophages C13, C36, D3, D20, C18, D3, S8, C21, C16, and D6.

Immunological relationships: Member of Resistance Group I.

Other properties. Particle size 8 to 12 millimicrons. Not affected by 26.3 per cent urea solution. Little or no inactivation by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes. Lysis completely inhibited by 0.25 per cent solution of sodium citrate.

Literature. Burnet and McKie, Jour. Path. and Bact., 36, 1933, 299-306, 307-318, 37, 1933, 179-181; Burnet et al., Austral Jour. Exp. Biol. and Med. Sci., 15, 1937, 227-268.

2. *Phagus minor* H. (loc. cit., 141) From Latin *minor*, lesser.

Common names: Bacteriophage C13, C8, and D44.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease. Large plaques, 8 to 12 mm in diameter, with wide shelving edges.

Serological relationships: Cross reactions with bacteriophages C8 and D44 but not with bacteriophages S13, C36, D3, D20, D13, C18, D3, S8, C21, C16, D6.

Immunological relationships: Member of Resistance Group I.

Other properties. Particle size, 15 to 20 millimicrons. Completely inactivated by 1:25,000 methylene blue in 2 mm layer 20 cm from 100 candle-power light for 30 minutes. Specific soluble substance formed in lysed cultures blocks phage-antiphage reaction.

Literature. Burnet, Jour. Path. and Bact., 36, 1933, 307-318, Brit. Jour. Exp. Path., 14, 1933, 100-108.

3. *Phagus parvus* H. (loc. cit., 142). From Latin *parvus*, small.

Common names: Bacteriophage C36, S18, C38, M, and C37 of Burnet.

Hosts: *Escherichia coli* Castellani and Chalmers; *Shigella dysenteriae* Castellani and Chalmers.

Induced disease. Moderately large plaques, 2 to 6 mm in diameter, with distinct halo.

18. *Phagus contumax* spec. nov. From Latin *contumax*, refractory, in reference to ability of this bacteriophage to withstand heating sufficient to destroy accompanying host cells.

Common name: *Erwinia aroideae* bacteriophage.

Host: *Erwinia aroideae* Holland.

Insusceptible species: *Agrobacterium tumefaciens* Conn, *Bacterium formosanum* Okabe, *Erwinia carotovora* Holland, *Pseudomonas andropogoni* Stapp, *P. solanacearum* Smith, *P. tomato* Burkholder, *Xanthomonas campestris* Dowson, *X. citri* Dowson, *X. malvacearum* Dowson, *X. nakatae* Dowson, *X. phaseoli* Dowson, *X. ricinicola* Dowson

Geographical distribution: Formosa (Taiwan)

Induced disease: Very small plaques, 0.1 to 1.0 mm (mostly less than 0.5 mm) in diameter.

Thermal inactivation: Resists heating at 60° C for 30 minutes without appreciable loss of titer, but host organism is killed by this treatment.

Other properties. Optimum temperature for increase, about 25° C. This bacteriophage may be prepared by heating centrifuged cultures at 60° C for 30 minutes as efficiently as by filtration to remove bacteria.

Literature: Matsumoto, Trans. Nat. Hist. Soc. Formosa, 29, 1939, 317-338, 50, 1940, 89-98; 31, 1941, 145-154, Matsumoto and Sawada, *ibid.*, 28, 1938, 247-256

19. *Phagus maldis* H. (*loc. cit.*, 152) From New Latin *mala*, corn (maize), host of *Bacterium stewarti*.

Common name: *Bacterium stewarti* bacteriophage; *Phytomonas stewarti* bacteriophage; *Aplanobacter stewarti* bacteriophage.

Host: *Bacterium stewarti* E. F. Smith (= *Pseudomonas stewarti* E. F. Smith, *Phytomonas stewarti* Bergey et al. and *Aplanobacter stewarti* McCulloch).

Geographical distribution: United States

Induced disease: In *Bacterium stewarti*, variation or loss of yellow color, change of viscosity of growth, reduction or loss of virulence. Infection of corn plants by seed-borne *Bacterium stewarti* is much reduced by treating seeds with this bacteriophage before they are planted.

Thermal inactivation: Above 65° C in 30 minutes.

Other properties: Infective in dilutions to 10<sup>-7</sup>. Soon lost from cultures maintained at pH 3.85 to 4.00, or on Ivanoff's medium, which contains oxidizing compounds.

Literature: Thomas, *Phytopath.*, 25, 1935, 371-372; *Science*, 88, 1938, 56-57; *Phytopath.*, 50, 1940, 602-611.

20. *Phagus enteritidis* H. (*loc. cit.*, 153). From name of host.

Common names: *Salmonella enteritidis* bacteriophage 1, 12, or 33; Group A bacteriophages.

Hosts: *Salmonella enteritidis* Castellani and Chalmers, *S. gallinarum* Bergey et al., *Shigella dysenteriae* Castellani and Chalmers.

Induced disease. Plaques of medium size, usually with surrounding translucent halo.

Immunological relationships: Member of Resistance Group A; host individuals that have acquired resistance to this bacteriophage are resistant to lines 12 and 33, but susceptible to *Salmonella enteritidis* bacteriophages 8, 20, and 11, as well as to other strains of Resistance Groups B, C, and D

Literature: Burnet, *Jour. Path. and Bact.*, 52, 1929, 15-42

21. *Phagus commutabilis* H. (*loc. cit.*, 153). From Latin *commutabilis*, variable, in reference to differences within Resistance Group B, typified by this bacteriophage.

Common names: *Salmonella enteritidis* bacteriophage 8, 18, 28, 31, 34, 38; Group B bacteriophages.

Hosts: *Salmonella enteritidis* Castellani

II Abt., 67, 1926, 236-242; 71, 1927, 302-311, 79, 1929, 354-370; Kent, *Phytopath.*, 27, 1937, 871-902; Muncie and Patel, *Phytopath.*, 20, 1930, 280-305.

14 *Phagus solanacearum* H (loc. cit., 118) From name of host.

Common name: *Pseudomonas solanacearum* bacteriophage.

Host *Pseudomonas solanacearum* Smith.

Geographical distribution: Formosa (Taiwan)

Induced disease: Medium size plaques on plate cultures of *Pseudomonas solanacearum*

Serological relationships: When injected into rabbits, this bacteriophage stimulates the production of a specific precipitating antibody not giving cross reactions with anti-bacterial antibodies. Antiphagic serum inactivated at 90° C in 10 minutes

Thermal inactivation: At 63° C in 10 minutes (61° C in 30 minutes; 66° C in about 1 minute)

Other properties: Optimum temperature for increase, 31° C

Literature: Matsumoto and Okabe, *Jour. Plant Prot.*, 22, 1935, 15-20, *Jour. Soc. Trop. Agr.*, 7, 1935, 130-139, 9, 1937, 203-213

15 *Phagus citri* H (loc. cit., 149) From name of host

Common name *Xanthomonas citri* bacteriophage

Host *Xanthomonas citri* Dowson, the citrus canker organism

Geographical distribution: Formosa (Taiwan)

Induced disease: Lysis This bacteriophage has been isolated from soil under diseased trees, and once from infected leaves. It may play a role in the destruction of the citrus canker organism in the soil.

Other properties: Optimum temperature for increase, 30° C

Literature: Matsumoto and Okabe,

*Agriculture and Horticulture*, 12, 1937, 2055-2059.

16. *Phagus pruni* H. (loc. cit., 151). From name of host.

Common name: *Xanthomonas pruni* bacteriophage.

Host: *Xanthomonas pruni* Dowson.

Geographical distribution: United States (from soil beneath infected peach trees).

Induced disease: Lysis in broth cultures; plaques on agar cultures, but characteristics of plaques not described.

Other properties: Estimated diameter 11 millimicrons in broth. Resists dilution to 1:10<sup>6</sup> or more.

Literature: Anderson, *Phytopath.*, 18, 1928, 144; Thornberry, *ibid.*, 25, 1935, 938-946.

17. *Phagus deformans* H. (loc. cit., 151). From Latin *deformare*, to disfigure, in reference to malformation of infected host cells.

Common name *Erwinia carotovora* bacteriophage.

Host: *Erwinia carotovora* Holland.

Insusceptible species: *Agrobacterium tumefaciens* Conn, except in some early tests with possibly mixed bacteriophages; *Erwinia amylovora* Winslow et al., *E. melonis* Holland, *Salmonella pullorum* Bergery et al., *S. gallinarum* Bergery et al., *Shigella dysenteriae* Castellani and Chalmers, *Xanthomonas pruni* Dowson

Geographical distribution: United States (Michigan).

Induced disease: In *Erwinia carotovora*, cells reduced in motility, agglutinated, malformed, some elongated, others swollen, bulged at one end, bulged in middle, or enlarged and spherical.

Other properties: Resists dilution to 1:10<sup>5</sup>, and storage in sterile medium at room temperature for 5½ months.

Literature: Coons and Kotila, *Phytopath.*, 15, 1925, 357-370; Mallmann and Hemstreet, *Jour. Agr. Res.*, 25, 1921, 599-602.

25. *Phagus testabilis* H. (*loc. cit.*, 155). From Latin *testabilis*, able to bear witness, in reference to evidence that this bacteriophage has given, by virtue of its easy destruction when heated in spores, against the hypothesis of frequent spontaneous origin of bacteriophage from the bacterial host.

Common name: *Bacillus megatherium* bacteriophage.

Host: *Bacillus megatherium* De Bary.

Geographical distribution: United States.

Induced disease: Plaques 0.5 mm or less in diameter, with surrounding translucent zone.

Thermal inactivation: *In vitro*, at 75° C in 10 minutes. Spores from infected cultures, after being heated for 10 minutes at 80° C, regularly give rise to subcultures that do not show the presence of this bacteriophage spontaneously during subsequent growth but that are susceptible to lysis if the bacteriophage is again introduced.

Literature: Adant, *Compt. rend. Soc. Biol.*, Paris, 29, 1928, 1246; Cowles, *Jour. Bact.*, 20, 1930, 15-23.

26. *Phagus indomitus* H. (*loc. cit.*, 156). From Latin *indomitus*, unrestrained, in reference to the ability of this bacteriophage to increase after heat treatment of infected spores.

Common name: *Bacillus mycoides* bacteriophage.

Host: *Bacillus mycoides* Flügge, some strains

Insusceptible species: *Bacillus cereus* Frankland and Frankland, *B. subtilis* Cohn emend. Prazmowski, *B. megatherium* De Bary, *B. anthracis* Cohn emend. Koch. Some strains of *B. mycoides*.

Geographical distribution: United States.

Induced disease: Large plaques, with some secondary growth of host organism.

Thermal inactivation: *In vitro*, at 75° C in 10 minutes. Spores from infected cultures, heated at 90° C for 10 minutes give

no bacteriophage on grinding, but lytic cultures when grown.

Literature: Lewis and Worley, *Jour. Bact.*, 32, 1936, 195-198.

27. *Phagus subvertens* H. (*loc. cit.*, 156). From Latin *subvertere*, to subvert, in reference to suspected action of this bacteriophage in causing running-out of alfalfa fields through destruction of nodule organisms.

Common name: *Rhizobium leguminosarum* bacteriophage.

Host: *Rhizobium leguminosarum* Frank. It has been shown that this bacteriophage is unable to increase in clover roots without the nodule-forming organism, *R. leguminosarum*, and that the bacteriophage plays no obviously essential role in nodule formation.

Induced disease: Very small plaques, with edges not sharply defined.

Thermal inactivation: At 60° C in 30 minutes.

Other properties: Not inactivated by drying for 2 months.

Literature: Gerretsen et al., *Cent. f. Bakt.*, II Abt., 60, 1923, 311-316; Grjns, *ibid.*, 71, 1927, 248-251; Hitchner, *Jour. Bact.*, 19, 1930, 191-201; Vandecaveye and Katznelson, *Jour. Bact.*, 31, 1936, 465-477.

28. *Phagus ineptus* H. (*loc. cit.*, 157). From Latin *ineptus*, unsuitable, in reference to inability of this bacteriophage to adapt itself to lysis of strain RW of its host.

Common name: *Streptococcus bacteriophage* R.

Host: *Streptococcus cremoris* Orla-Jensen, strain R.

Insusceptible species: *Streptococcus cremoris*, strain RW.

Geographical distribution: New Zealand.

Induced disease: Plaques 0.25 to 0.6 mm in diameter.

Serological relationships: Antiserum specific for *Streptococcus bacteriophage* RW

and Chalmers, *Shigella dysenteriae* Castellani and Chalmers, *Shigella gallinarum* Weldin, *Salmonella typhosa* White.

Induced disease: Small plaques with sharp edges, or moderately large plaques with characteristic halo.

Immunological relationships: Member of Resistance Group B, host individuals that have acquired resistance to this bacteriophage are resistant to lines 18, 28, 31, 34, and 38, but susceptible to *Salmonella enteritidis* bacteriophages 1, 20, and 11, as well as to other strains of Resistance Groups A, C, and D.

Literature: Burnet, Jour. Path. and Bact., 32, 1929, 15-42.

22. *Phagus tertius* H (*loc cit*, 151)  
From Latin *tertius*, third, in reference to the third Resistance Group of *Salmonella enteritidis* bacteriophages, Group C, typified by this bacteriophage.

Common names: *Salmonella enteritidis* bacteriophage 20, 25, 32, 35, Group C bacteriophages.

Hosts: *Salmonella enteritidis* Castellani and Chalmers, *S. gallinarum* Bergey et al., *Shigella dysenteriae* Castellani and Chalmers.

Induced disease: Plaques of small size, with sharp edges.

Immunological relationships: Member of Resistance Group C. Host individuals that have acquired resistance to this bacteriophage are resistant to lines 25, 35, and 32, but susceptible to *Salmonella enteritidis* bacteriophages of Resistance Groups A, B, and D.

Literature: Burnet, Jour. Path. and Bact., 32, 1929, 15-42.

23. *Phagus dubius* H (*loc cit*, 155)  
From Latin *dubius*, doubtful, in reference to uncertainty of distinction between Resistance Groups C and D.

Common names: *Salmonella enteritidis* bacteriophage 11, 13, Group D bacteriophages.

Hosts: *Salmonella enteritidis* Castellani and Chalmers, *Shigella dysenteriae* Cas-

tellani and Chalmers, *Shigella gallinarum* Weldin.

Induced disease: Very large plaques, up to 8 mm in diameter on 1.2 per cent agar.

Immunological relationships: Member of Resistance Group D. Host individuals that have acquired resistance to this bacteriophage are resistant to line 13, but susceptible to *Salmonella enteritidis* bacteriophages of Resistance Groups A, B, and C.

Literature: Burnet, Jour. Path. and Bact., 32, 1929, 15-42.

24. *Phagus indicens spec. nov.* From Latin *indicare*, to disclose or indicate, in reference to diagnostic use of this bacteriophage in identifying V forms of the typhoid bacillus.

Common name: Phage Q151.

Host: *Salmonella typhosa* White (= *Bacillus typhosus* Zopf).

Insusceptible species: W forms of the typhoid organism and various *Salmonella* species.

Geographical distribution: Canada.

Induced disease: In *Salmonella typhosa*, small plaque formation (lysis) and complete inhibition of growth in cultures of the V form (bearing Vi antigen; resisting O agglutination) and no lysis or restraining effect on growth of the W form (lacking Vi antigen, agglutinated by O antiserum). In the presence of the virus, mixed cultures are quickly transformed since only W variants can increase. Pure V cultures can be identified by the test for their complete inhibition, this inhibition is regularly followed by secondary growth representing the pure W form of the host, a readily formed variant.

Filterability: Passes Seitz EK filter.

Other properties: Filtrate active in dilutions to  $10^{-9}$  or  $10^{-11}$ .

Literature: Craigie, Jour. Bact., 31, 1936, 56 (Abst.); Craigie and Brandon, Jour. Path. and Bact., 43, 1946, 233-248, 249-250.

bacteriophage to remain viable under certain adverse conditions.

Common name: *Streptococcus bacteriophage C*.

Hosts: *Streptococcus* 646, 594, 756, 806.

Geographical distribution: United States (Ohio, Massachusetts, Connecticut).

Induced disease: Small plaques, the largest about 1.0 mm in diameter.

Serological relationships: Specific neutralization, but no cross reactions with streptococcus bacteriophages A, B, and D.

Thermal inactivation: At 63° to 65° C in 1 hour.

Other properties: Withstands storage in 1:200 phenol at about 5° C for at least 261 days; equally resistant to storage in 1:10,000 sodium ethyl mercurithiosalicylate (merthiolate), or to storage without preservatives.

Literature: Evans, U. S. Pub. Health Ser., Public Health Reports, 49, 1934, 1386-1401.

### 33. *Phagus michiganensis spec. nov.*

From name of state, Michigan, where this bacteriophage was first isolated.

Common name: *Streptococcus bacteriophage D*.

Host: *Streptococcus* 693.

Geographical distribution: United States (Michigan)

Induced disease: Small plaques, about 0.75 mm in diameter, edges clear-cut, centers clean.

Serological relationships: Specific neutralization, but no cross neutralization with streptococcus bacteriophages A, B, and C.

Thermal inactivation. At 60° to 63° C in 1 hour.

Other properties: Withstands storage at about 5° C for at least 261 days.

Literature. Evans, U. S. Pub. Health Ser., Public Health Reports, 49, 1934, 1386-1401.

### 34. *Phagus fragilis*, H (*loc. cit.*, 150).

From Latin *fragilis*, fragile, in reference

to easy destruction of this bacteriophage by light and by concentrated urea solutions.

Common names: *Staphylococcus bacteriophage* Au2, Au3, Au4, or D, perhaps bacteriophage H of Gratia.

Hosts: *Staphylococcus aureus* Rosenbach and *Staphylococcus albus* Rosenbach

Geographical distribution: United States.

Induced disease: Small plaques, 0.2 to 1.0 mm in diameter, with sharp edges

Serological relationships: Cross-neutralization reactions with staphylococcus bacteriophages Au1, Au3, Au4, and D, but not with staphylococcus bacteriophages Au21, Au12, A, B, C, or bacteriophage C16.

Thermal inactivation: At about 57° C in 30 minutes.

Other properties: Particle diameter 50 to 75 millimicrons. Readily inactivated photodynamically. Completely inactivated by 27 per cent urea solution in 1 hour at 37° C. Lysis not inhibited even by 15 per cent sodium citrate in agar medium.

Literature: Burnet and Lush, Jour. Path. and Bact., 40, 1935, 455-469; Burnet and McKie, Austral. Jour. Exp. Biol. and Med. Sci., 6, 1929, 21-31; Fisk, Jour. Inf. Dis., 71, 1942, 153-160.

35. *Phagus intermedius* H (*loc. cit.*, 160). From Latin *intermedius*, intermediate, in reference to position of this bacteriophage between staphylococcus bacteriophages that multiply readily in broth cultures of host organisms and those that do not.

Common name: *Staphylococcus bacteriophage* Au21.

Host: *Staphylococcus aureus* Rosenbach.

Geographical distribution: Australia.

Induced disease: Small plaques, 0.1 to 0.3 mm in diameter, with sharp edges.

Serological relationships: Specific neutralization reaction but no cross-neutralization reaction with staphylococcus bacteriophages Au2 or Au12.

and its strain RW1 are ineffective in neutralizing this bacteriophage.

Immunological relationships: Cultures of host-strain R, after exposure to this bacteriophage, furnish subcultures only partly resistant to this bacteriophage and completely susceptible to streptococcus bacteriophage RW and its substrain RW1.

Literature: Whitehead and Hunter, Jour. Path. and Bact., 44, 1937, 337-347

29. *Phagus streptococci* II (*loc cit.*, 158) From generic name of host.

Common name: Streptococcus bacteriophage RW

Host: *Streptococcus cremoris* Orla-Jensen, strain RW

Geographical distribution: New Zealand

Induced disease: Plaques 0.25 to 0.6 mm in diameter.

Thermal inactivation: At 70° to 75° C, time not recorded, probably 30 minutes (pH 6.0)

Literature: Whitehead and Hunter, Jour. Path. and Bact., 44, 1937, 337-347

Strains: One variant has been described and distinguished from the type variety, *typicus* II (*loc cit.*, 158).

29a. *Phagus streptococci* var *virilis* II (*loc cit.*, 158). From Latin *virilis*, vigorous. Common name: Strain RW1 of streptococcus bacteriophage RW. Differing from the type variety in being able to increase at the expense of strain RW1 of *Streptococcus cremoris* (Whitehead and Hunter, Jour. Path. and Bact., 44, 1937, 337-347)

30. *Phagus maculans* *spec. nov.* From Latin *maculare*, to speckle, in reference to tiny plaques produced by this bacteriophage

Common name: Streptococcus bacteriophage A

Hosts: Streptococcus 616, 751, 775

Geographical distribution: United States (Massachusetts)

Induced disease: Plaques exceedingly

minute, scarcely visible to the unaided eye.

Serological relationships: Specific antisera neutralize but there is no cross reaction with respect to streptococcus bacteriophage B, C, or D.

Thermal inactivation: At 60° C in 1 hour

Other properties: Withstands storage at about 5° C for at least 145 days with but little loss of virulence.

Literature: Evans, Science, 80, 1934, 40-41; U.S.P.H.S., Public Health Reports, 49, 1934, 1386-1401

31. *Phagus lacerans* *spec. nov.* From Latin *lacerare*, to tear, in reference to ragged edges of plaques produced by this bacteriophage.

Common name: Streptococcus bacteriophage B

Hosts: Streptococcus 563,639: *Streptococcus mucosus* Howard and Perkins.

Insusceptible species: *Streptococcus erysipelatos* Rosenbach.

Geographical distribution: United States (Wisconsin).

Induced disease: Medium size plaques, the largest about 3 mm in diameter, edges ragged, centers clean.

Serological relationships: Specific neutralization, but no cross reactions with streptococcus bacteriophages A, C, and D.

Thermal inactivation: At 60° C in 1 hour

Other properties: Withstands storage at about 5° C for at least 261 days

Literature: Clark and Clark, Jour. Bact., 11, 1926, 89; Proc. Soc. Exp. Biol. and Med., 24, 1927, 635-639; Colvin, Jour. Inf. Dis., 51, 1932, 17-29; Evans, U.S.P.H.S., Public Health Reports, 49, 1934, 1386-1401, Jour. Bact., 39, 1910, 507-604; Schwartzman, Jour. Exp. Med., 45, 1927, 497-500

32. *Phagus tolerans* *spec. nov.* From Latin *tolerans*, tolerating, in reference to the unusual ability of this streptococcus

and McKie, Austral. Jour. Exp. Biol. and Med. Sci., 6, 1929, 21-31.

39. *Phagus durabilis* H. (*loc. cit.*, 162). From Latin *durabilis*, lasting, in reference to the stability of this bacteriophage in concentrated urea solution and other unfavorable media.

Common name: *Staphylococcus bacteriophage C*.

Host: *Staphylococcus albus* Rosenbach.

Geographical distribution: Australia.

Induced disease: Plaques 2.0 to 3.0 mm in diameter. Vitreous change in peripheral zone.

Serological relationships: Cross-neutralization reaction with *staphylococcus bacteriophage C'*, and less strongly with B, but not with Au2 or A.

Immunological relationships: Colonies of *Staphylococcus albus* appearing after lysis with this bacteriophage furnish organisms resistant to it but susceptible to *staphylococcus bacteriophages A, B, and D*.

Thermal inactivation: At 61° to 63° C in 30 minutes.

Other properties: Not readily inactivated photodynamically; not completely inactivated by 27 per cent urea solution in 1 hour at 37° C; lysis not inhibited even by 1.5 per cent sodium citrate in agar medium.

Literature: Burnet and Lush, Jour. Path. and Bact., 40, 1935, 455-469; Burnet and McKie, Austral. Jour. Exp. Biol. and Med. Sci., 6, 1929, 21-31; Rakieta et al., Jour. Bact., 32, 1936, 505-518.

40. *Phagus liber* H. (*loc. cit.*, 163). From Latin *liber*, independent, in reference to demonstrated independence of this virus, its bacterial host, and its diptherous superhost, in respect to origin.

Common name: *Staphylococcus muscae bacteriophage*.

Host: *Staphylococcus muscae* Glaser.

Geographical distribution: United States

Induced disease: Lysis in broth cul-

tures; plaques in agar cultures, but characteristics of plaques not recorded.

Thermal inactivation: At a little above 50° C in 5 minutes.

Other properties: A characteristic nucleoprotein has been isolated from lysed *staphylococci*. Sedimentation constant,  $650 \times 10^{-13}$  cm dyne<sup>-1</sup> sec.<sup>-1</sup>, corresponding to a molecular weight of about 300,000,000. Denatured at acidities beyond pH 5.0. Digested by chymotrypsin, not by trypsin. Apparent density, about 1.20. Diffusion coefficient, varying with dilution.

Literature: Glaser, Amer. Jour. Hygiene, 27, 1938, 311-315; Northrop, Jour. Gen. Physiol., 21, 1938, 335-366; Shope, Jour. Exp. Med., 45, 1927, 1037-1044; Wyckoff, Jour. Gen. Physiol., 21, 1938, 367-373.

41. *Phagus cholerae* H. (*loc. cit.*, 164). From former name of host.

Common name: *Vibrio comma bacteriophage*.

Host: *Vibrio comma* Winslow et al (formerly *V. cholerae* Neisser); Indian strains usually carry this bacteriophage, but Chinese and Japanese strains lack it, are susceptible, and upon inoculation become lysogenic.

Geographical distribution: India.

Induced disease: In both R and S forms of *Vibrio comma*, no plaques on ordinary agar plates, but vibrios become lysogenic. Egg-white in 1:25 dilution enhances activity enough to allow visible lysis, occasional plaques, or stippling at the site of inoculation.

Immunological relationships: *Vibrio comma* organisms that have been infected with this bacteriophage and are resistant to its further action are still susceptible to cholera bacteriophages A, C, and D.

Literature: White, Jour. Path. and Bact., 44, 1937, 276-278

42. *Phagus celer* H. (*loc. cit.*, 164). From Latin *celer*, quick, in reference to relatively quick action of this bacteriophage.

Other properties: Not readily inactivated photodynamically; completely inactivated by 27 per cent urea solution in 1 hour at 37° C; lysis inhibited by 1 per cent sodium citrate in agar medium but not by 0.5 per cent or lower concentrations.

Literature: Burnet and Lush, Jour. Path. and Bact., 40, 1935, 455-469

36. *Phagus caducus* H. (*loc. cit.*, 160)  
From Latin *caducus*, perishable, in reference to the easy destruction of this bacteriophage by concentrated urea solutions.

Common name: *Staphylococcus bacteriophage* Au12.

Host: *Staphylococcus aureus* Rosenbach

Geographical distribution: Australia

Induced disease: Small plaques, 0.2 to 0.5 mm in diameter, with sharp edges

Serological relationships: Cross-neutralization reactions with *staphylococcus bacteriophages* Au11 and Au13, but not with *staphylococcus bacteriophages* Au2, Au21, A, and C. Antiserum to *staphylococcus bacteriophage* B gives no neutralization of Au12, though the reciprocal reaction occurs to 1:200 dilution.

Other properties: Not readily inactivated photodynamically; completely inactivated by 27 per cent urea solution in 1 hour at 37° C; lysis inhibited by as little as 0.25 per cent sodium citrate in agar.

Literature: Burnet and Lush, Jour. Path. and Bact., 40, 1935, 455-469

37. *Phagus alpha* H. (*loc. cit.*, 161)  
From Greek equivalent of common name.  
Common name: *Staphylococcus bacteriophage* A.

Host: *Staphylococcus albus* Rosenbach

Geographical distribution: Australia

Induced disease: Plaques of medium size, 1.5 to 2.5 mm in diameter, with hazy periphery.

Serological relationships: Specific neutralization reaction, but no cross-neutralization reactions with *staphylococcus bacteriophages* Au2, B, or C.

Immunological relationships: Colonies of *Staphylococcus albus* appearing after lysis with this bacteriophage are resistant to *staphylococcus bacteriophages* B, C, and D.

Thermal inactivation: At 68° to 70° C in 30 minutes.

Other properties: Not readily inactivated photodynamically; not completely inactivated by 27 per cent urea solution in 1 hour at 37° C; lysis not inhibited even by 1.5 per cent sodium citrate in agar.

Literature: Burnet and Lush, Jour. Path. and Bact., 40, 1935, 455-469; Burnet and McKie, Austral. Jour. Exp. Biol. and Med. Sci., 6, 1929, 21-31.

38. *Phagus beta* H. (*loc. cit.*, 162).  
From Greek equivalent of common name.

Common name: *Staphylococcus bacteriophage* B.

Host: *Staphylococcus albus* Rosenbach.

Geographical distribution: Australia.

Induced disease: Plaques of medium size, 0.7 to 1.5 mm in diameter, with sharp edges.

Serological relationships: Specific neutralization reaction, but no cross-neutralization reaction with respect to *staphylococcus bacteriophages* Au2, Au12, A, or C, except that antiserum made with Au12 neutralizes this bacteriophage in low dilutions (See *Phagus caducus*).

Immunological relationships: Colonies appearing after lysis of *Staphylococcus albus* with this bacteriophage furnish organisms susceptible to *staphylococcus bacteriophages* A and D.

Thermal inactivation: At 63° to 65° C in 10 minutes.

Other properties: Readily inactivated photodynamically; completely inactivated by 27 per cent urea solution in 1 hour at 37° C; lysis not inhibited even by 1.5 per cent sodium citrate in agar medium.

Literature: Burnet and Lush, Jour. Path. and Bact., 40, 1935, 455-469; Burnet

Potato: Rich, creamy spreading growth.

Indole not formed.

Nitrites not produced from nitrates.

Ammonia is produced.

Acid from glucose, maltose, starch, glycerol and mannitol. No acid from lactose or sucrose.

Cellulose is attacked.

Aerobic, facultative.

Optimum temperature 20°C.

Source: Isolated from soils in Utah.

Habitat: Soil.

8a. *Pseudomonas effusa* var. *non-liquefaciens* Kellerman et al (*loc. cit.*). A non-liquefying variety that acts more slowly on litmus milk.

Source: Soils from Utah.

9. *Pseudomonas reptilivorous* Caldwell and Ryerson. (*Jour. Bact.*, 39, 1940, 335.) From Latin, *reptile*, a reptile and *voro*, to devour, destroy.

Rods. 0.5 by 1.5 and 2.0 microns, occurring singly, in pairs and in short chains and having rounded ends. Actively motile with two to six polar flagella. Gram-negative.

Gelatin colonies. After 24 hours, small, circular, smooth, entire. Liquefaction with a yellowish-green fluorescence.

Gelatin stab. Infundibuliform liquefaction becoming stratiform. Putrid odor present.

Agar cultures: Circular, smooth, glistening, slightly raised, butyrous, translucent, 2 mm in diameter.

Agar slant: Growth abundant, smooth, film-form, glistening, butyrous and translucent.

Broth. Turbid with pellicle and sediment. Putrid odor.

Litmus milk: Alkaline, peptonization, complete reduction. Disagreeable odor.

Potato. Growth moderate, spreading, glistening, yellowish-gray to creamy. Disagreeable odor. Medium becomes brownish-gray.

Indole not formed.

Nitrates not produced from nitrates.

Hydrogen sulfide not produced.

Slightly acid, becoming alkaline in glucose. No acid from arabinose, xylose, lactose, sucrose, maltose, trehalose, raffinose, mannitol, dulcitol, inositol and salicin.

Starch not hydrolyzed.

Pathogenic for guinea pigs and rabbits, horned lizards, Gila monsters and chuck-wallas.

Temperature relations: Optimum 20° to 25°C. Maximum 37°C.

Distinctive characters: Yellowish-green fluorescence present in meat infusion media. Pathogenic.

Source: Isolated in a bacterial disease of horned lizards and Gila monsters.

Habitat: Pathogenic for lizards.

10. *Pseudomonas synchyanea* (Ehrenberg) Migula. (*Vibrio synchyaneus* Ehrenberg, *Berichte u.d. Verh. d. k. Preuss. Akad. d. Wissensch. z. Berlin*, 5, 1840, 202; *Vibrio cyanogenes* Fuchs, *Magazin für die gesamte Tierheilkunde*, 7, 1841, 190; *Bacillus synchyaneus* Schroeter, *Kryptogam. Flora von Schlesien*, 3, 1, 1886, 157; *Bacillus cyanogenus* Zopf, *Die Spaltpilze*, 3 Aufl., 1885, 86; Migula, in Engler and Prantl, *Die natürl. Pflanzenfam.*, 1, 1a, 1895, 29; *Bacterium synchyaneum* Lehmann and Neumann, *Bakt. Diag.*, 1 Aufl., 2, 1896, 275; *Pseudomonas cyanogenes* Holland, *Jour. Bact.*, 5, 1920, 224.) From Greek, *syn*, with; *kyaneos*, dark blue, dark.

Rods with rounded ends, occurring singly, occasionally in chains, 0.7 by 2.0 to 4.0 microns. Motile with two to four polar flagella. Gram-negative.

Gelatin colonies: Flat, bluish, translucent.

Gelatin stab: Surface growth shiny, grayish blue. The medium is colored steel-blue with greenish fluorescence. Gelatin is liquefied. Some strains do not liquefy.

Agar slant: Grayish-white streak. The medium takes on a bluish-gray color with slight fluorescence.

Common name: Cholera bacteriophage A.

Host: *Vibrio comma* Winslow et al., smooth types, except non-agglutinable vibrios.

Geographical distribution: India

Induced disease. Lysis in 2 hours, followed by abundant secondary growth. Only smooth elements of the culture are attacked.

Serological relationships. Antigenically distinct from cholera bacteriophage C.

Immunological relationships. Secondary growth resistant to this virus, but susceptible to cholera bacteriophages C and D.

Other properties. Selectively inactivated by specific polysaccharide of smooth strains, not by a lipid emulsion that is effective against cholera bacteriophage C. Active in dilution of  $1:10^3$  or  $1:10^4$ . Multiplication rate,  $n \times 10^4$  in 2 hours.

Literature: Asheshov et al., Indian Jour. Med. Res., 20, 1933, 1127-1157; White, Jour. Path. and Bact., 45, 1936, 591-593.

43 *Phagus effrenus* H. (*loc. cit.*, 165). From Latin *effrenus*, unbridled, in reference to the ability of this bacteriophage to attack all tested strains of the cholera organism.

Common name: Cholera bacteriophage C.

Host: *Vibrio comma* Winslow et al., all strains.

Geographical distribution: India.

Induced disease. Sometimes death without lysis. When lysis occurs, it is rarely complete and is followed by secondary resistant growth.

Serological relationships. Antigenically distinct from cholera bacteriophage A.

Immunological relationships. Secondary growth resistant to this bacteriophage, but susceptible to cholera bacteriophages A and D.

Other properties. Selectively inactivated by lipid from smooth strain of host, but not by specific polysaccharide

Active in dilution of  $1:10^3$  or  $1:10^4$ . Multiplication rate,  $n \times 10^4$  in 2 hours.

Literature: Asheshov et al., Indian Jour. Med. Res., 20, 1933, 1127-1157; White, Jour. Path. and Bact., 45, 1936, 591-593.

44 *Phagus lentus* H. (*loc. cit.*, 166). From Latin *lentus*, slow, in reference to the relatively slow and incomplete lysis induced by this bacteriophage.

Common name: Cholera bacteriophage D.

Host: *Vibrio comma* Winslow et al.

Geographical distribution: India.

Induced disease. Incomplete lysis in about 5 hours, followed, in rough cultures, by slow development of resistant secondary growth.

Immunological relationships. Secondary growth resistant to this bacteriophage, but susceptible to cholera bacteriophages A and C.

Other properties. Not inactivated by specific polysaccharide effective against cholera bacteriophage A, nor by lipid effective against cholera bacteriophage C. Multiplication rate,  $n \times 10^3$  in 2 hours.

Literature: Asheshov et al., Indian Jour. Med. Res., 20, 1933, 1127-1157; White, Jour. Path. and Bact., 45, 1936, 591-593.

45 *Phagus diphtheriae* H. (*loc. cit.*, 167). From name of host.

Common name: *Corynebacterium diphtheriae* bacteriophage.

Host: *Corynebacterium diphtheriae* Lehmann and Neumann, many strains, especially 122 of 127 Australian type II *gravis* isolates, type I *gravis* isolates are lysogenic (carriers), all intermediate isolates are susceptible.

In-susceptible species: *Corynebacterium diphtheriae*, all tested *mitis* isolates, except 2 lysogenic. A strain of *C. diphtheriae* from Swan Hill, 200 miles north of Melbourne, was found to be resistant to this bacteriophage and to the small-

plaque diphtheria bacteriophage, *P. futilis*.

Geographical distribution: Australia.

Induced disease: In *Corynebacterium diphtheriae* on agar, plaques 1.0 to 1.5 mm in diameter, with shelving edge. A few resistant bacterial colonies often appear in the central clear area.

Literature: Keogh et al., Jour. Path. and Bact., 46, 1938, 565-570; Smith and Jordan, Jour. Bact., 21, 1931, 75-88; Stone and Hobby, Jour. Bact., 27, 1934, 403-417.

46. Phagus *futilis* H. (loc. cit., 168). From Latin *futilis*, vain, in reference to regular appearance of resistant organisms

in plaques on agar cultures lysed by this bacteriophage.

Common name: Small-plaque diphtheria bacteriophage.

Host: *Corynebacterium diphtheriae* Lehmann and Neumann, *gravis* type I isolates and all but 5 *gravis* type II isolates.

Insusceptible species: All tested intermediate and *mitis* strains of *C. diphtheriae*.

Geographical distribution: Australia

Induced disease: In *Corynebacterium diphtheriae* on agar, pin-point plaques or confluent plaques, with confluent growth of secondary, resistant organisms.

Literature: Keogh et al., Jour. Path. and Bact., 46, 1938, 565-570.

SUBORDER II. *Phytophagineae subordo novus.*

Viruses infecting higher plants; vectors typically homopterous or hemipterous insects (leafhoppers, aphids, white flies, true bugs) or thysanopterous insects (thrips). From Greek *phagein*, to eat, and *phyton*, a plant.

*Key to the families of suborder Phytophagineae.*

1. Inducing yellows-type diseases, vectors typically cicadellid or fulgorid leafhoppers.  
Family I. *Chlorogenaceae*, p 1145.
2. Inducing mosaic diseases; vectors typically aphids.  
Family II. *Marmoraceae*, p.1163.
3. Inducing ringspot diseases; vectors unknown.  
Family III. *Annulaceae*, p. 1212.
4. Inducing leaf-curl diseases, vectors typically white flies.  
Family IV. *Rugaceae*, p 1218.
5. Inducing leaf-savoying diseases, vectors, true bugs.  
Family V. *Savoiaceae*, p 1221.
6. Inducing spotted wilt, vectors, thrips.  
Family VI. *Lethaceae*, p. 1223

## FAMILY I. CHLOROGENACEAE HOLMES EMEND.

(Handb. Phytopath. Viruses, 1939, 1.)

## DELLIDAE and FULGORIDAE)

*Key to the genera of family Chlorogenaceae.*

- I True Yellows Group. Viruses inducing diseases usually characterized by stimulation of normally dormant and adventitious buds to produce numerous slender shoots with long internodes and by chlorosis without spotting; invaded parts abnormally erect in habit. Vectors cicadellid leafhoppers so far as known.  
Genus I. *Chlorogenus*, p 1146
- II. Peach X-Disease Group. Viruses inducing diseases characterized by rosetting of foliage and sometimes death of host.  
Genus II. *Carpophthora*, p 1151
- III Phloem-Necrosis Group. Viruses inducing diseases characterized by progressive degeneration of the host plant or by wilting and sudden death; sometimes by root discoloration. Vectors cicadellid leafhoppers so far as known.  
Genus III. *Morus*, p 1153
- IV. Yellow-Dwarf Group. Viruses inducing diseases characterized by chlorotic effects somewhat resembling true mottling but often more diffuse. Vectors cicadellid (agallian) leafhoppers.  
Genus IV. *Aurogenus*, p 1151.
- V. Fiji-Disease Group. Viruses inducing diseases characterized by marked vascular proliferation. The vector of one is known to be a leafhopper of the subfamily Delphacinae, family FULGORIDAE.  
Genus V. *Gallo*, p. 1157.

- VI. Stripe-Disease Group. Viruses inducing diseases characterized by chlorotic striping; hosts grasses. Vectors, cicadellid and fulgorid leafhoppers.  
Genus VI. *Fractilinea*, p. 1159.

Genus I. *Chlorogenus* Holmes.

(Loc. cit., 1.)

Viruses of the Typical Yellows Group, inducing diseases usually characterized by stimulation of normally dormant and adventitious buds to produce numerous slender shoots with long internodes, by chlorosis without spotting, or by both growth of numerous slender shoots and chlorosis. Invaded parts abnormally erect in habit. Affected flowers often virescent. Hosts, dicotyledonous plants. Vectors, so far as known, exclusively cicadellid leafhoppers. Generic name from Greek *chloros*, light green or yellow, and suffix, *gen*, signifying producing, from Greek *genos*, descent.

The type species is *Chlorogenus callistephi* Holmes.

Key to the species of genus *Chlorogenus*.

1. *Chlorogenus callistephi* Holmes.  
(Handb. Phytopath. Viruses, 1939, 2.)  
From New Latin *Callistephus*, generic name of the China aster.

Common names: Aster-yellows virus, lettuce white-heart virus, *Erigeron*-yellows virus.

Hosts: *Callistephus chinensis* Nees, the China aster, is the host that has been studied most. 170 or more species in 38 different families of dicotyledonous plants have been shown susceptible. Lettuce, endive, carrot, buckwheat, parsnip, and New Zealand spinach are among the hosts of economic importance

Insusceptible species. All tested species of the family *Leguminosae* and some species of all other tested families have appeared naturally immune

Geographical distribution: U. S., Canada, Bermuda, Japan, and Hungary. In California the celery-yellows strain of this virus replaces the type.

Induced disease: In most host species the characteristics of disease are clearing of veins, followed by chlorosis of newly formed tissues, stimulation of normally dormant buds to growth, malformation, virescence of flowers, sterility, and upright growth habit. Stimulation of new

mally dormant buds to adventitious growth and abnormally erect habit are the most constant features. Chlorosis is absent or inconspicuous in some hosts.

Transmission: By leafhopper, *Macrosteles divinus* (Uhl.) (= *Cicadula sexnotata* (Fall.), *C. divisa* (Uhl.)) (CICADELLIDAE). Incubation period, about 2 weeks. Some strains of this virus are transmitted also by the leafhoppers *Thamnotettix montanus* Van D. and *T. geminatus* Van D. (CICADELLIDAE). By grafting. By dodder. Not through seeds of diseased plants. Not by mechanical inoculation of plants, but virus has been passed from insect to insect mechanically in *Macrosteles divinus*, juice from viruliferous insects contains little virus just after inoculation, but the effective concentration increases at least 100-fold between the 2nd and 12th day of a 17-day incubation period, it seems greatest before the insects begin to infect the aster plants on which they are maintained.

Thermal inactivation. In juice from viruliferous insects, at about 40° C in 10 minutes, at 25° C in 2 to 3 hours. In plant tissues, at 38° to 42° C, in 2 to 3 weeks, cured plants fully susceptible to reinfection. In insect vector, *M. divinus*, at 31° C in 12 days.

Other properties. Virus in juices derived from insects is more stable at 0° C than at 25° C or when frozen; at 0° C it withstands storage 24, not 48, hours in 0.85 per cent NaCl solution at pH 7.0 but most of the virus is inactivated in this time; it withstands dilution 1:1000 in neutral 0.85 per cent NaCl solution, for brief (less than 5-minute) exposures, it remains viable over the range from pH 5 to 9.

Literature. Black, *Phytopath.*, 31, 1911, 120-135; 33, 1913, 2 (Abstr.); Johnson, *ibid.*, 31, 1911, 619-656; Kunkel, *Am. Jour. Bot.*, 15, 1920, 616-705; Contrib. Boyce Thompson Inst., 3, 1931, 85-123, 4, 1932, 405-414; *Am. Jour. Bot.*, 24, 1937, 316-327; 28, 1911, 761-769; Linn, Cornell Agr. Exp. Sta. (Ithaca), Bull.

742, 1940; Ogilvie, Bermuda Dept. Agr., Agr. Bull. 6, 1927, 7-8; Severin, *Hilgardia*, 3, 1929, 543-583; *Phytopath.*, 20, 1930, 920-921; *Hilgardia*, 7, 1932, 163-179; 8, 1934, 305-325, 339-361; *Phytopath.*, 30, 1940, 1049-1051; *Hilgardia*, 14, 1942, 411-440; Severin and Haasis, *Hilgardia*, 8, 1934, 329-335.

Strains. Two variant strains, one found in nature, the other derived experimentally, have been given varietal names to distinguish them from the type variety, *vulgaris* H. (*loc. cit.*, 2):

1a. *Chlorogenus callistephi* var. *californicus* H. (*loc. cit.*, 3). From California, name of state in which this strain was first recognized. Common name: Celery-yellows strain of aster-yellows virus. Differing from the type variety by ability to infect celery (*Apium graveolens* L.—UMBELLIFERAE) and zinnia (*Zinnia elegans* Jacq.—COMPOSITAE) (Kunkel, Contrib. Boyce Thompson Inst., 4, 1932, 405-414; Severin, *Hilgardia*, 3, 1929, 543-583; 8, 1934, 305-325).

1b *Chlorogenus callistephi* var. *attenuatus* H. (*loc. cit.*, 4). From Latin *attenuatus*, weakened. Common name: Heat-attenuated strain of aster-yellows virus. Differing from the type variety by inducing less severe chlorosis and less uprightness of new growth in affected aster plants (Kunkel, *Am. Jour. Bot.*, 24, 1937, 316-327).

2. *Chlorogenus australiensis* comb. nov. From Australia, name of continent. Synonym. *Galla australiensis* H. (*loc. cit.*, 107).

Common names: Tomato big-bud virus; virecence virus; perhaps also stowbore virus, tobacco stollbur or montar virus, eggplant little-leaf virus.

Hosts: SOLANACEAE—*Datura stramonium* L., Jimson weed; *Lycopersicon esculentum* Mill., tomato; *Nicotiana glauca* L., tobacco; *Solanum melongena* L., eggplant; *S. nigrum* L., black nightshade. Recently a long list of species in this and

other families have been reported as susceptible to virescence virus, presumed to be an isolate of tomato big-bud virus. (Hill, Jour. Coun. Sci. Ind. Res., 16, 1943, 85-92).

Geographical distribution: Australia, especially New South Wales; viruses causing somewhat similar diseases have been reported also from the Crimea and the northwestern United States.

Induced disease: In tomato, flowers erect, virescent, calyx bladder-like, pollen sterile; floral proliferation. Growth of axillary shoots stimulated. New leaves progressively smaller. Youngest leaves yellowish-green in color, especially at their margins; usually purplish underneath. Hypertrophy of inner phloem. No intracellular inclusions. Fruit reddens imperfectly and becomes tough and woody. Roots appear normal. In *Solanum nigrum*, axillary shoots numerous, leaves small, internal phloem adventitious. In tobacco, plants dwarfed; leaves recurved, distorted, twisted, thickened, brittle, yellowish green, hanging down close to stem; small leaves on shoots from axillary buds; proliferation and virescence of flowering parts; chlorotic clearing of veins as early effect of disease; upper surface of foliage appears glazed; some necrosis of veins, in old leaves, near tips and margins or on midrib; viable seed rarely produced; calyx bladder-like, floral axis may form short branches bearing small leaves; disease sometimes called bunched top.

Transmission: By leafhopper, *Thamnotettix argentata* Evans (CICADELLIDAE). Experimentally by budding and other methods of grafting. Not by inoculation of expressed juice.

Literature: Cobb, Agr. Gaz. New South Wales, 18, 1902, 410-414; Dana, Phytopath., 30, 1940, 866-869; Hill, Jour. Austral. Inst. Agr. Sci., 6, 1940, 199-200; Jour. Council Sci. Ind. Res., 10, 1937, 309-312; 16, 1943, 85-92; Michailowa, Phytopath., 25, 1935, 539-558; Rischkov et al., Ztschr. Pflanzenkr., 43, 1933, 496-

498; Samuel et al., Phytopath., 23, 1933, 641-653.

3. *Chlorogenus persicae* H. (loc. cit., 5). From New Latin *Persica*, former generic name of peach.

Common names: Peach-yellow virus, little-peach virus.

Hosts: ROSACEAE—*Prunus persica* (L.) Batsch, peach; *P. salicina* Lindl., Japanese plum; and all other tested species of the genus *Prunus*.

Geographical distribution: Eastern United States and Canada, south to North Carolina. First occurred near Philadelphia in this country. Origin perhaps oriental; introduction in oriental plums suspected. Not in Europe.

Induced disease: In peach, clearing of veins, production of thin erect shoots bearing small chlorotic leaves, followed by death in a year or two. In early stages of the disease there is premature ripening of fruit. In Japanese plum, systemic infection but no obvious symptoms.

Transmission: By the leafhopper, *Macropsis trimaculata* (Fitch) (CICADELLIDAE). By budding; virus spreads down stem from point of bud insertion faster than up. Not by inoculation of expressed juice, despite numerous attempts. Not by pollen of diseased trees.

Immunological relationships: Presence of peach-yellow virus immunizes tree against little-peach virus, formerly considered an independent entity.

Thermal inactivation: In peach tissues, at 34° to 35° C in 4 to 5 days; at 44° C in 30 minutes, at 47° C in 10 minutes; at 50° C in 3 to 4 minutes; at 56° C in 15 seconds.

Other properties: Trees and bud sticks may be treated safely with heat sufficient to kill the virus. Cured trees are susceptible to reinfection.

Literature: Blake, N. J. Agr. Exp. Sta., Bull. 226, 1910; Kunkel, Contrib. Boyce Thompson Inst., 5, 1933, 19-28; Phytopath., 26, 1936, 201-219, 809-830, 28, 1938, 491-497; Manns, Trans. Peninsula Hort. Soc., 23, 1933, 17-19; Manns and Manns,

*ibid.*, 24, 1934, 72-76, McCubbin, Pennsylvania Dept. Agr., Gen. Bull. 332, 1924

Strains: Numerous strains of peach-yellow virus probably exist in nature. One of these has been given a varietal name, distinguishing it from the type variety, *tulgaris* H. (*loc. cit.*, 5):

3a. *Chlorogenus persicae* var. *microperisica* H. (*loc. cit.*, 6). From Greek *micros*, small, and New Latin *Persica*, former generic name of peach. Common name Little-peach strain of peach-yellow virus. Differing from the type variety by tendency to cause a mild type of disease, characterized by distortion of young leaves, production of many short branches on main trunk, later yellowing of mature leaves, twiggy growth, shoots slightly less erect than in typical peach yellows (Kunkel, *Phytopath.*, 26, 1936, 201-219, 20, 1936, 809-830; 28, 1938, 491-497, Manns, *Trans. Peninsula Hort. Soc.*, 23, 1933, 17-19; 24, 1934, 72-76)

4. *Chlorogenus solani* H. (*loc. cit.*, 7). From New Latin *Solanum*, generic designation of potato. Synonym: *Chlorophthora solani* McKinney, *Jour. Washington Acad. Sci.*, 34, 1914, 151.

Common names: Potato witches'-broom virus, potato wilding or semi-wilding virus.

Hosts: **SOLANACEAE**—*Solanum tuberosum* L., potato. Experimentally, also **SOLANACEAE**—*Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco; *N. glutinosa* L.; *N. rustica* L. **APOCYNACEAE**—*Vinca rosea* L., periwinkle. **CHENOPODIACEAE**—*Beta vulgaris* L., sugar beet

Geographical distribution: United States (Montana, Washington), Russia

Induced disease: In potato, increasingly pronounced flavescence in new leaflets on one or more stems, production of new dwarfed leaflets with marginal flavescence on stems with unusually long internodes and enlarged nodes, growth of spindling axillary and basal branches

profuse blooming and fruiting, lack of dormancy in tuber buds, formation of many small underground tubers as well as some aerial tubers; plants grown from diseased tubers form thread-like stems and small simple leaves; infected plants survive several seasons, with progressive degeneration. In tomato, experimentally, extreme leaf dwarfing, marginal flavescence of leaves and abnormally numerous axillary branches, stems become hollow and die; plants do not survive long after infection. In tobacco, experimentally, slender axillary branches with dwarfed leaves, flowers on spindling pedicels, numerous, small, later leaves flavescence or marginally flavescence

Transmission: By tuber-core grafts with prepatent period of 29 to 114 days. By stem grafts. By dodder, *Cuscuta campestris* Yuncker (**CONVOLVULACEAE**). Not by inoculation of expressed juice. Not by *Macrostelus divinus* (Uhl.) (**CICADELLIDAE**). No insect vector is known. Not through seeds of diseased tomatoes

Thermal inactivation at 42° C in 13 days, in tissues of *Vinca rosea*; at 36° C in 6 days in small potato tubers.

Literature: Hungerford and Dina, *Phytopath.*, 14, 1921, 372-383, Kunkel, in *Virus Diseases*, Cornell Univ. Press, Ithaca, N. Y., 1913, 63-82; *Proc. Am. Philosoph. Soc.*, 86, 1913, 470-475, McLarty, *Scient. Agr.*, 6, 1926, 395, Whipple, *Montana Agr. Exp. Sta. Bull.* 130, 1919; Young, *Science*, 66, 1927, 301-306; *Am. Jour. Bot.*, 16, 1929, 277-279, Young and Morris, *Jour. Agr. Res.*, 36, 1928, 835-851.

5. *Chlorogenus santali* H. (*loc. cit.*, 8). From New Latin *Santalum*, generic designation of sandal

Common names: Sandal spike-disease virus, sandal spike-rosette virus.

Hosts: **SANTALACEAE**—*Santalum album* L., sandal. Spike-like diseases have been found also in **RHAMNACEAE**—*Zizyphus oenoplia* Mill., **SAPINDACEAE**—*Dolomieuia viscosa* Jacq. **VIR-**

## II. Inducing rosette formation characteristically, but not tattering of affected foliage.

### 2. *Carpophthora rosettae*.

1. *Carpophthora lacerans* (Holmes) McKinney. (*Marmor lacerans* Holmes, Handb. Phytopath. Viruses, 1939, 82; McKinney, Jour. Washington Acad. Sci., 34, 1944, 152.) From Latin *lacerare*, to lacerate, in reference to characteristic foliage injury.

Common name: Peach X-disease virus; virus of peach yellow-red virosis.

Hosts: *ROSACEAE*—*Prunus persica* (L.) Batsch, peach; *P. virginiana* L., chokecherry.

Geographical distribution: United States, Canada.

Induced disease: In peach, foliage normal each spring but yellowish areas appear in June at base of leaves; affected trees appear lighter green than neighboring healthy trees; discolored spots occur at random on the leaf blade, becoming red and yellow with remainder of leaf becoming chlorotic; the discolored areas usually fall out, leaving the foliage tattered; subsequently, affected leaves drop except at tips of branches; young trees may die, older ones survive indefinitely. Fruit either shrivels and falls or ripens prematurely, with bitter flavor and no viable seed. In chokecherry, conspicuous premature reddening of foliage, development of fruits with dead embryos in the pits, in the second and third seasons after infection, duller colors of foliage, rosettes of small leaves on terminals, death follows the advanced stage of disease.

Transmission: By budding. Not by inoculation of expressed juice. No insect vector has been reported.

Literature: Berkeley, Div. of Botany and Plant Path., Science Service, Dominion Dept. Agr., Ottawa, Canada, Publication 678, 1941; Boyd, U. S. Dept. Agr., Plant Dis. Rep., 22, 1938, 334, Hildebrand, Contrib. Boyce Thompson Inst., 11, 1941, 485-496; Hildebrand and Palmer, U. S. Dept. Agr., Plant Dis. Rep.,

22, 1938, 394-396; Hildebrand et al., Handbook of virus diseases of stone fruits in North America, Michigan Agr. Exp. Sta., Misc. Publ., 1942, 21-24; Stoddard, Connecticut Agr. Exp. Sta., Circ. 122, 1938, 54-60; Proc. Connecticut Pomol. Soc., 48, 1938, 29-32.

2. *Carpophthora rosettae* (Holmes) comb. nov. (*Chlorogenus rosettae* H., *nomen nudum*, Phytopath. 29, 1939, 434; *Nanus rosettae* H., Handb. Phytopath. Viruses, 1939, 125.) From rosette, common name of induced disease, from French, diminutive of rose, a rose.

Common name: Peach-rosette virus.

Hosts: *ROSACEAE*—*Prunus persica* (L.) Batsch, peach; *P. communis* Fritsch, almond; *P. domestica* L., plum. Experimentally, also—*APOCYNACEAE*—*Vinea rosea* L., periwinkle. *ROSACEAE*—*P. americana* Marsh., wild plum, *P. armeniaca* L., apricot; *P. cerasus* L., cherry; *P. pumila* L., sand cherry. *SOLANACEAE*—*Lycopersicon esculentum* Mill., tomato; *Nicotiana glutinosa* L.

Geographical distribution: United States (Georgia, Alabama, South Carolina, Tennessee, West Virginia, Missouri, Oklahoma).

Induced disease: In peach, sudden wilting and death, or growth of abnormally short stems bearing dwarfed leaves with clearing and thickening of veins, followed by death in a few months.

Transmission: By budding. By dodder, *Cuscuta campestris* Yunker. Not by inoculation of expressed juice. Not through soil. No insect vector is known.

Immunological relationships: No protection is afforded by previous infection of peach trees with *Chlorogenus persicae*, peach-yellows virus.

Thermal inactivation: At 50° C in 10 minutes (in tissues of peach). Rosetted trees are abnormally susceptible to heat

injury and heat treatments cure peach-rossette disease only in recently infected trees.

Literature: Kunkel, *Phytopath.*, 26, 1936, 201-219, 800-830; in *Virus Diseases*,

Cornell Univ. Press, Ithaca, N. Y., 1943, 63-82; McClintock, *Jour. Agr. Res.*, 24, 1923, 307-316, *Phytopath.*, 21, 1931, 373-386, Smith, U. S. Dept. Agr., Div. Veg. Path., Bull. 1, 1891.

### Genus III. *Morsus* gen. nov.

Alfalfa-Dwarf Group, viruses inducing diseases characterized in general by sudden wilting and death or by gradual decline of vigor with foliage of darker green color than normal. Vectors, like those of the typical yellows subgroup, cicadellid leafhoppers so far as known. Generic name from Latin *morsus*, sting or vexation.

The type species is *Morsus suffodiens* spec. nov.

#### Key to the species of genus *Morsus*.

#### I. Affecting alfalfa and grape

1. *Morsus suffodiens*.

#### II. Affecting tobacco.

2. *Morsus reprimens*.

#### III. Affecting elm.

3. *Morsus ulmi*.

1. *Morsus suffodiens* spec. nov. From Latin *suffodere*, to sap or undermine, in reference to process leading to sudden collapse of long infected, but sometimes not obviously injured, grape vines as well as to progressive decline in size of infected alfalfa plants, the foliage of which may remain green to the last.

Common names: Alfalfa-dwarf virus, lucerne dwarf-disease virus, virus of Pierce's disease of the grape, virus of Anaheim disease.

Hosts: *LEGUMINOSAE*—*Medicago sativa* L., alfalfa (lucerne). *VITACEAE*—*Vitis vinifera* L., grape.

Geographical distribution: United States.

Induced disease: In alfalfa, leaves small but green, plant progressively smaller, wood of roots discolored yellow, transpiration decreased; wilting may occur; starch of root diminished, plant eventually succumbs, thinning stand prematurely. In grape, dark green color of leaves retained along veins, not between them, or no abnormality in appearance of foliage; wilting and sudden death of plant in summer of second year. In late summer of first year, there may be

dying leaf margins and dying back of cane tips.

Transmission: By budding and root grafting. By leafhoppers, *Draculacephala mineria* Ball, *Carnoccephala fulgida* Nott, *C. triguttata* Nott, *Heliochara delta* Oman, *Neololla circellata* (Baker), *N. gothica* (Sign.), *N. confuens* (Uhler), *N. heiroglyphica* (Say), and *Cuerna occidentalis* Oman and Beamer (*CICA-DELLIDAE*), these vectors all belong to the subfamily *Amblycephalinae*, all tested species of this, but none of any other, subfamily have proved capable of transmitting this virus. Not by inoculation of expressed juice. Not through soil.

Literature: Frazier, *Phytopath.*, 34, 1944, 1000-1001; Hewitt, *Phytopath.*, 29, 1939, 10, 31, 1941, 862; Blue Anchor, 18, 1941, 16-21, 36; Hewitt et al., *Phytopath.*, 32, 1942, 8; Houston et al., *Phytopath.*, 32, 1942, 10; Milbrath, Calif. Dept. Agr., 20th Ann. Rept., Bull. 28, 1940, 671; Pierce, U. S. Dept. of Agr., Div. of Veg. Path., Bull. 2, 1892, 1-222; Welmer, *Phytopath.*, 21, 1931, 71-75; 27, 1937, 697-702, *Jour. Agr. Res.*, 47, 1933, 331-368; 63, 1936, 323-347; 65, 1937, 87-104.

2. *Morsus reprimens* spec. nov. From Latin *reprimere*, to restrain, check, or curb, in reference to the inhibiting effect on growth of the host plant, tobacco.

Common name: Tobacco yellow-dwarf virus.

Hosts: *SOLANACEAE*—*Nicotiana tabacum* L., tobacco, *N. rustica* L., Indian tobacco; *N. trigonophylla* Dun. Experimentally, also *N. glauca* Grah. (symptomless) and *N. glutinosa* L.

Geographical distribution: Australia (Victoria, New South Wales, South Australia, and southern Queensland).

Induced disease: In tobacco, internodes of stem shortened, leaves small; downward bending of tips and rolling under of margins of young apical leaves; young leaves darker than normal at first, bunched, later appear ribbed; leaves become yellow-green, pale first between veins; old leaves rugose, thickened, later savoyed. Root system small, roots slightly brown externally and in the region of the phloem. Affected plants may survive the winter and show diseased new growth in the spring.

Transmission: By grafting and budding. By nymphs and adults of the leaf-

hopper, *Thamnotettix argentata* (Evans) (*CICADELLIDAE*).

Literature: Dickson, Australia, Council Sci. Indust. Res., Pamphlet 14, 1929, 22; Hill, Australia, Journal of the Council Sci. Indust. Res., 10, 1937, 223-230; 14, 1941, 181-186; 15, 1942, 13-25.

3. *Morsus ulmi* spec. nov. From Latin *ulmus*, elm.

Common name: Elm phloem-necrosis virus.

Host: *URTICACEAE*—*Ulmus americana* L., American elm.

Geographical distribution: United States (Ohio, Indiana, Illinois, Missouri, Tennessee, Kentucky, and West Virginia).

Induced disease: In elm, gradual decline over a period of 12 to 18 months before death or sudden wilt, drying of leaves, and death within 3 to 4 weeks. All ages susceptible, from seedling to large tree.

Transmission: By patch grafting. Not by inoculation of expressed juice.

Literature: Leach and Valteau, U. S. Dept. Agr., Plant Dis. Rept., 23, 1939, 300-301; Swingle, Phytopath., 30, 1940, 23.

#### Genus IV. *Aureogenus* Black.

(Proc. Am. Philos. Soc., 88, 1944, 141.)

Viruses of the Yellow-Dwarf Group, inducing diseases characterized by yellowing without typical mosaic-type mottling. Vectors agallian leafhoppers (*CICADELLIDAE*). Generic name from Latin *aureus*, yellow or golden, and *genus*, group.

The type species is *Aureogenus vastans* (Holmes) Black.

#### Key to the species of genus *Aureogenus*.

- I. Mechanically transmissible in some hosts by rubbing methods of inoculation.  
Not producing enlarged veins or club-leaf in clover.
  1. *Aureogenus vastans*.
- II. Not known to be transmissible by rubbing methods of inoculation.
  - A. Producing enlarged veins in clover
    2. *Aureogenus magnivena*.
  - B. Producing club-leaf in clover.
    3. *Aureogenus clavifolium*.

Broth: Turbid with marked fluorescence.

Litmus milk: Unchanged. In association with lactic acid bacteria the milk takes on a deep blue color.

Potato: Yellowish-gray, shiny layer, becoming bluish-gray. The medium becomes bluish-gray.

Indole not formed.

Nitrites not produced from nitrates  
Aerobic, facultative

Optimum temperature 25°C

Habitat: The cause of blue milk

11. *Pseudomonas schuylkilliensis* Chester. (*Bacillus fluorescent schuylkilliensis* Wright, Memoirs, Natl Acad Sci., 7, 1895, 448, Chester, Determinative Bact., 1901, 320) From M. L. of the Schuylkill (River)

Synonyms: *Pseudomonas capsulata* Chester, Man. Determin Bact., 1901, 322 (*Bacillus fluorescent capsulatus* Pottien, Ztschr. f. Hyg., 11, 1896, 140), *Pseudomonas dermatogenes* Fuhrmann, Cent. f. Bakt., II Abt., 17, 1906, 356

Short rods, with rounded ends, occurring singly, in pairs and in chains. Motile, possessing a polar flagellum. Gram-negative.

Gelatin colonies: Grayish-white, translucent, with brownish center, radiate margin, becoming bluish green.

Gelatin stab: Slow crateriform liquefaction, with blue green fluorescence.

Agar slant: Grayish, translucent growth. Medium shows greenish fluorescence.

Broth: Turbid, with slight pellicle and blue-green fluorescence. Stringy sediment.

Litmus milk: Coagulated, with slow reduction of litmus; peptonized.

Potato: Brownish, spreading, viscid, thick.

Indole is formed (trace)

Nitrites not produced from nitrates

Aerobic, facultative

Does not grow at 35° to 36°C

Source: Isolated from Schuylkill River water.

Habitat: Water.

12 *Pseudomonas chlororaphis* (Guignard and Sauvageau) Bergey et al. (*Bacillus chlororaphis* Guignard and Sauvageau, Compt. rend. Soc. Biol. Paris, 1, 10 sér., 1894, 841; Bergey et al., Manual, 3d ed., 1930, 166; also see Lasseur and Dupaix-Lasseur, Trav. Lab. Microbiol. Fac. Pharm. Nancy, Fasc. 9, 1936, 35.) From Greek, *chlōros*, greenish yellow; *raphis*, needle

Rods: 0.8 by 1.5 microns, with rounded ends, occurring singly and in pairs. Motile with polar flagella. Gram-negative.

Gelatin colonies: Circular, viscid, transparent, glistening, lobate margin, with fluorescent corona. Dissociates readily (Lasseur and Dupaix-Lasseur, loc. cit.).

Gelatin stab: Stratiform liquefaction.

Broth: Turbid, fluorescent, with crystals of green, water-soluble chlororaphine.

Litmus milk: Coagulation. Peptonization. Crystals of chlororaphine form in the central part of the culture.

Potato: Citron-yellow layer. Crystals of chlororaphine are formed.

Nitrates reduced to nitrites.

Indole not formed

Pigment formation: Asparagine, potassium phosphate, glycerol, sulfate of magnesium and sulfate of iron are indispensable to the formation of crystals of chlororaphine.

Aerobic, facultative. Optimum temperature 25° to 30°C

Pathogenic for laboratory animals. Exotoxin formed

Habitat: Water.

13 *Pseudomonas myxogenes* Fuhrmann. (Cent. f. Bakt., II Abt., 17, 1907, 356) From Greek, *myxa*, mucus, genos, to beget, M. L. slime-producing

Rods: 0.4 to 0.5 by 1.0 to 1.5 microns, occurring singly and in pairs. Motile, possessing a bundle of five to seven polar flagella. Gram-negative.

Filterability: Passes Berkefeld W filter.

Other properties: Virus viable at 23 to 27° C less than 13 hours after extraction of juice from diseased plant; not infective after drying in leaf tissues.

Literature: Barrus and Chupp, *Phytopath.*, 12, 1922, 123-132; Black, *Am. Potato Jour.*, 11, 1931, 148-152; Cornell Univ. Agr. Exp. Sta., Mem. 209, 1937, 1-23; *Phytopath.*, 28, 1938, 863-874; *Am. Jour. Bot.*, 27, 1940, 386-392; *Am. Potato Jour.*, 18, 1941, 231-233; *Phytopath.*, 53, 1943, 363-371; *Genetics*, 28, 1943, 200-209; *Proc. Am. Philos. Soc.*, 83, 1944, 132-144; Hansing, Cornell Univ. Agr. Exp. Sta., Bull. 792, 1943; Price and Black, *Am. Jour. Bot.*, 28, 1941, 594-595; Taylor, *Am. Potato Jour.*, 16, 1938, 37-40; Walker and Larson, *Jour. Agr. Res.*, 69, 1935, 259-280; Watkins, *Jour. Econ. Ent.*, 32, 1939, 561-564; Cornell Univ. Agr. Exp. Sta., Bull. 758, 1941, 1-21; Younkin, *Am. Potato Jour.*, 19, 1942, 6-11.

Strains: Beside the type variety, *Aureogenus vastans* var. *vulgare* Black (*Am. Jour. Bot.*, 27, 1940, 391), on which the species is based, two distinctive strains have been given varietal names:

1a. *Aureogenus vastans* var. *agalliae* Black. (*Am. Potato Jour.*, 18, 1941, 233.) From New Latin *Agallia*, generic name of vector of this strain. Common name: New Jersey strain of potato yellow-dwarf virus. Differing from the type especially in its distinctive vector, the leafhopper, *Agallia constricta* Van Duzee, which is incapable of transmitting the type strain, and in not being transmitted by *Aceratagallia sanguinolenta* (Provancher), common vector of the type variety. Experimentally, transmitted also by *Agallia quadripunctata* (Provancher), perhaps rarely by *Agalliopsis novella* (Say). Differing but little from the type in effects on potato (var. Green Mountain) and *Nicotiana rustica* but more definitely in effects on crimson clover, in affected plants of which a rusty-brown necrosis

along the veins, not induced by the type strain, is always present in some degree.

1b. *Aureogenus vastans* var. *lethale* Black. (*Am. Jour. Bot.*, 27, 1940, 391.) From Latin *lethalis*, causing death. Common name: Strain B5 of potato yellow-dwarf virus. Differing from the type variety especially in a tendency to induce in *Nicotiana rustica*, experimentally, brown primary lesions with necrotic gray centers, systemic yellowing, extensive necrosis of veins, collapse of large areas of leaf, and sometimes death of the host; not known to occur in nature as a separate strain, but readily isolated as a variant from strains collected in nature.

2. *Aureogenus magnivena* Black. (*Proc. Am. Philos. Soc.*, 83, 1944, 144.) From Latin *magnus*, large, and *vena*, vein.

Common name: Clover big-vein virus.

Host: Experimentally, *LEGUMINOSAE*—*Trifolium incarnatum* L., crimson clover.

In susceptible species: *SOLANA-CEAE*—*Nicotiana rustica* L., Indian tobacco; *Solanum tuberosum* L., potato.

Geographical distribution: United States (presumably, Washington, D. C.).

Induced disease: In crimson clover, experimentally, unevenly thickened veins which are depressed below the upper surface of the leaf; these enlarged veins, best observed from below, sometimes bear enations that arise from their lower surfaces, leaves often curl upward and inward marginally, in summer, yellowing of leaves progresses from margins inward, the yellow color being later replaced in part by red or purple red; petioles undulating; plants dwarfed; internodes shortened; no clearing of veins, no rusty-brown necrosis.

Transmission: Not by inoculation of expressed juice. By leafhoppers, *Agalliopsis novella* (Say), *Agallia constricta* Van Duzee, *A. quadripunctata* (Provancher); not by *Aceratagallia sanguinolenta* (Provancher) (*CICADELLIDAE*).

1. *Aureogenus vastans* (Holmes) Black (*Marmor vastans* Holmes, Handb. Phytopath. Viruses, 1939, 94; Black, Proc. Am. Philos. Soc., 88, 1944, 141.) From Latin *vastare*, to devastate

Common name: Potato yellow-dwarf virus

Hosts: **SOLANACEAE**—*Solanum tuberosum* L., potato **COMPOSITAE**—*Chrysanthemum leucanthemum* L., var. *pinnatifidum* Lecoq and Lamotte, daisy; *Rudbeckia hirta* L., black-eyed Susan. **CRUCIFERAE**—*Barbarea vulgaris* R. Br., common winter cress. **LEGUMINOSAE**—*Trifolium pratense* L., red clover Experimentally to numerous species in these and other families.

Geographical distribution: Northeastern United States and southeastern Canada.

Induced disease: In potato, yellowing of leaves, necrosis of stem, dwarfing of plant, the stem, if split, shows rusty specks especially at nodes and apex; the apex dies early, tubers are few, small, close to the stem, often cracked, with flesh discolored by scattered brown specks, seed tubers tend to remain unrotted in the ground, becoming hard and glassy, some of them do not germinate in warm soil, others produce shoots that die before reaching the surface, giving poor stands. In *Chrysanthemum leucanthemum* var. *pinnatifidum*, at first, clearing of veins, later, young leaves distorted, thick, stiff, small; petioles short, leaves erect, forming a rosette at the crown of the plant, with passing of the early phases of the disease, foliage tends to

veinal reddish-brown color on both leaf surfaces extending from the margins inwards; dwarfing of entire plant; death or a chronic disease characterized by milder manifestations without, however, vein enlargement or cupping of leaves. In *Nicotiana rustica* L., experimentally, yellowish primary lesions followed by clearing of veins and systemic chlorosis; the primary lesions facilitate quantitative estimation of concentrations of this virus.

Transmission: By inoculation of expressed juice, in the presence of finely powdered carborundum, to *Nicotiana rustica*; mechanical transmission very difficult in other hosts tested. By grafting. By clover leafhopper, *Aceratagallia sanguinolenta* (Provancher); experimentally, by other closely related leafhoppers, *Aceratagallia lyrata* (Baker), *A. obscura* Oman, and *A. currata* Oman; not (for the type variety of the virus) by *Agallia constricta* Van Duzee, very rarely by *Agallia quadripunctata* (Provancher) and *Agalliopsis norella* (Say) (**CICADELLIDAE**). The vector *Aceratagallia sanguinolenta* remains infective as an overwintering adult; incubation period not less than 6 days, commonly much longer; virus does not pass to progeny of viruliferous leafhoppers through eggs or sperm; this leafhopper varies genetically in ability to transmit.

Immunological relationships: No protection is afforded against necrotic effects of a testing strain of this virus (var. *lethale* Black) by prior inoculation of *Nicotiana rustica* with isolates of *Marmor medicaginis*, *M. cucumeris*, *M. upsalis*, *Annulus tabaci*, *A. orae*, or *A. dubius*, but the varieties *vulgare* Black and *agalliae* Black protect; these specifically protecting strains give no similar protection against formation of necrotic lesions by subsequently applied isolates of *Marmor tabaci*, *M. lethale*, *Annulus tabaci*, or *A. orae*.

Thermal inactivation: At 50 to 52° C in 10 minutes.

and after the period of obvious disease and infected plants may constitute an important reservoir. In *Trifolium incarnatum* L., crimson clover, experimentally, clearing of veins and yellowing of younger leaves (in summer the yellowing is usually replaced in part by an inter-

Ser., 3, 1924, 99-107; Lyon, *ibid.*, 3, 1921, 1-43; Hawaiian Planters' Rec., 12, 1915, 200; Mungomery and Bell, Queensland, Bur. Sugar Exp. Sta., Div. Path., Bull. 4, 1933; Ocfemia, Am. Jour. Bot., 21, 1924, 112-122.

2. *Galla queenslandensis* H. (*loc. cit.*, 109). From Queensland, where the induced disease was first studied

Common name: Sugar-cane dwarf-disease virus.

Host: GRAMINEAE—*Saccharum officinarum* L., sugar cane.

Geographical distribution: Queensland.

Induced disease: In sugar cane, young leaves marked with scattered chlorotic streaks, leaves stiff and erect, spindle twisted, abnormally short and pale. As leaves mature, streaks disappear, leaves become darker than normal green. In recently infected plants, vascular bundles are enlarged, irregular in shape, fused and characterized by abnormal proliferation of thin-walled lignified cells.

Literature: Bell, Queensland, Bur. Sugar Exp. Sta., Div. Path., Bull. 3, 1932.

3. *Galla anemones* H. (*loc. cit.*, 108). From Latin *anemone*, anemone or windflower.

Common name: Anemone-alloioophyll virus.

Hosts: RANUNCULACEAE—*Anemone nemorosa* L., vernal windflower; *A. ranunculoides* L., *A. trifolia* L.

Geographical distribution: Germany.

Induced disease: Leaves thickened and distorted, petioles thickened. Flowers distorted or not formed. Vascular bundles larger and more numerous than in healthy plants. Palisade cells short, chloroplasts smaller and fewer than normal.

Transmission. By needle puncture into rhizomes immersed in filtered juice of diseased plant. By contamination of soil with fragments of diseased leaves or rhizomes.

Literature: Klebahn, Bericht. d. Deutsch. Bot. Gesellschaft., 16, 1897, 527-536; Ztschr. wissenschaft. Biol., Abt. E., *Planta*, 1, 1926, 419-440; 6, 1928, 40-95; Phytopath. Ztschr., 4, 1932, 1-36; 9, 1936, 357-370.

4. *Galla verrucae* Blodgett. (Phytopath., 33, 1943, 30) From Latin *verruca*, wart. Originally spelled *verruca*, apparently by a typographical error, which was corrected twice on the following page, once in a statement that the genitive *verrucae* had been given as specific epithet.

Common name: Peach-wart virus.

Host: ROSACEAE—*Prunus persica* (L.) Batsch, peach.

Geographical distribution: United States (Idaho, Washington, Oregon).

Induced disease: In peach, no characteristic effect on foliage. Fruits blistered, wilted, later with warty outgrowths conspicuously raised. Affected tissues light tan to red, rough, cracked and russeted, or smooth. Gumming usual, often severe. Warty tissue superficial; underlying tissues coarse, filled with gum pockets, but not abnormal in flavor. Warty tissue may be hard and bony, but more often it is merely tougher than normal.

Transmission: By budding and inarching.

Literature: Blodgett, Phytopath., 31, 1941, 859-860 (Abst.); 33, 1943, 21-32.

5. *Galla zeae* McKinney. (Jour. Washington Acad. Sci., 34, 1944, 328) From Latin *zea*, a kind of grain

Common name: Wallaby-ear disease virus

Host: GRAMINEAE—*Zea mays* L., corn (maize).

Geographical distribution: South-eastern Queensland, Australia.

Induced disease. In corn (maize), small swellings on secondary veins on undersides of young leaves, spreading to base and tip of leaf along veins; plant dwarfed, becoming abnormally deep green and deficient in development of pollen, silk, cobs, and grain retarded in growth.

3. *Aureogenus clavifolium* Black (Proc. Am. Philos. Soc., 83, 1911, 141.) From Latin *clava*, club, and *folium*, leaf.

Common name: Clover club-leaf virus.

Host. Experimentally, *LEGUMINOSAE*—*Trifolium incarnatum* L., crimson clover.

Insusceptible species: *SOLANACEAE*—*Nicotiana rustica* L., Indian tobacco, *Solanum tuberosum* L., potato.

Geographical distribution: United States (Princeton, N. J.).

Induced disease: In crimson clover, experimentally, youngest leaves lighter green than normal, slow to unfold; leaf

margins yellowed or colored red or purple red; affected leaves narrow, smooth or savoyed; plant dwarfed, new shoots from leaf axils slightly stimulated; new growth of spindly stems and small leaves; no rusty-brown necrosis of veins, no obvious enlargement of veins, and no obvious clearing of veins at the onset of disease.

Transmission: Not by inoculation of expressed juice. By leafhopper, *Agallipus norcilla* (Say) (*CICADELLIDAE*); not by leafhoppers, *Accratagallia sanguinolenta* (Provancher), *Agallia constricta* Van Duzee, nor *A. quadripunctata* (Provancher) (*CICADELLIDAE*).

#### Genus V. *Galla Holmes*

(Loc. cit., 106)

Viruses of the Fiji-Disease Group, inducing diseases characterized by vascular proliferation. Generic name from Latin *galla*, a gall nut

The type species is *Galla fijensis* Holmes

#### Key to the species of genus *Galla*.

- I Infecting sugar cane.
  - A Inducing formation of conspicuous galls.
    - 1 *Galla fijensis*.
  - B Not inducing formation of conspicuous galls.
    - 2. *Galla queenslandensis*
- II Infecting anemone.
  - 3 *Galla anemones*.
- III Infecting peach.
  - 4. *Galla ferrugae*.
- IV Infecting corn.
  - 5. *Galla zeae*

1 *Galla fijensis* Holmes (Handb. Phytopath. Viruses, 1939, 106) From name of Fiji Islands

Common name: Fiji-disease virus

Host *GRAMINEAE*—*Saccharum officinarum* L., sugar cane

Geographical distribution: Fiji Islands, New South Wales, Java, Philippine Islands, New Guinea and New Caledonia

Induced disease: In sugar cane, galls on vascular bundles, formed by proliferation of phloem and nearby cells. Affected cells show characteristic spherical or oval inclusion bodies. Developing leaves shortened, crumpled, abnormally

dark green. Infected stools of cane become bushy. Roots small, bunched

Transmission: By leafhoppers, *Perkinsiella saccharicida* Kirk (in Queensland) and *P. rasilatrix* Breddin (in Philippine Islands) (*FULGORIDAE*, subfamily *Delphacinae*). Not by grafting. Not by inoculation of expressed juice. Not through eggs of *P. rasilatrix*. Cuttings taken from affected canes produce some healthy and some diseased plants, because virus does not become uniformly distributed throughout the host tissues.

Literature: Kunkel, Bull. Exp. Sta., Hawaiian Sugar Planters' Assoc., Bot.

maize-streak virus. Differing from the type strain in being specialized for attacking sugar cane, in which the type (from maize) tends to be localized or finally lost with resultant spontaneous recovery of the temporary host. The cane-streak strain usually spreads readily in the cane plant; leaves become much marked with broken, narrow, pale, longitudinal stripes and spots; stems remain unaffected. One variety of sugar cane, P O J 213, is resistant and, if infected, tends to recover. (McClellan, Intern. Soc. Sugar Cane Techn., Bull. 27, 1932; Proc. So. Afr. Sugar Techn. Assoc., 1936, 1-11; Storey, Rept. Imp. Bot. Conf., London, 1924, 132-144; Union So. Afr. Dept. Agr., Sci. Bull. 39, 1935, Ann. Appl. Biol., 17, 1930, 691-719.)

1b *Fractilinea maidis* var. *mitis* H. (loc. cit., 58). From Latin *mitis*, mild. Common name: Mottle strain of maize-streak virus. Differing from the typical strain by the mildness of the disease induced in corn (maize), transitory chlorotic mottling of newly developed leaves, followed by fading of mottling and production of apparently normal leaves. Young leaves, while mottled, are less rigid than normal and may not remain as nearly erect as healthy leaves (Storey, Ann. Appl. Biol., 24, 1937, 87-91.)

2. *Fractilinea oryzae* (Holmes) comb. nov. (*Marmor oryzae* Holmes, loc. cit., 64.) From Latin *oryza*, rice.

Common name: Rice dwarf-disease virus.

Hosts. GRAMINEAE—*Oryza sativa* L., rice. Experimentally, also *Alopecurus fulvus* L., *Avena sativa* L., oat; *Echinochloa crusgalli* Beauv. var. *edulis* Honda, *Panicum mitaceum* L.; *Poa pratensis* L.; *Secale cereale* L., rye; *Triticum vulgare* Vill., wheat.

Insusceptible species: GRAMINEAE—*Zea mays* L., corn (maize); *Hordeum vulgare* L., barley; *Setaria italica* Beauv.,

foxtail millet; *Andropogon sorghum* Brot. (= *Holcus sorghum* L.), sorghum.

Geographical distribution: Japan, Philippine Islands.

Induced disease: In rice, yellowish green spots along veins of young leaf, followed by chlorotic spotting and streaking of subsequently formed leaves. Growth stunted, internodes and roots abnormally short, forming a dwarf plant. Vacuolate intracellular bodies, 3 to 10 by 2.5 to 8.5 microns in size, close to nuclei of cells in affected tissues.

Transmission: By leafhoppers, *Nephotettix apicalis* var. *cincticeps* Uhler, *N. bipunctatus* Fabr., and *Deltocephalus dorsalis* Motsch. (CICADELLIDAE). Virus transmitted through some of the eggs but through none of the sperm of infected individuals of *N. apicalis*. Transfer from individuals thus infected through the egg to their progeny likewise demonstrated, even to the 7th generation. This is the only confirmed instance of transmission of a phytopathogenic virus through the eggs of an insect vector and is considered as evidence that the virus multiplies within the body of its vector as well as in its plant hosts. Incubation period in insect usually 30 to 45 days after first feeding on an infected plant, sometimes as short as 10 or as long as 73 days; nymphs from viruliferous eggs do not become infective until 7 to 38 (average 19) days after emergence. Transmission by inoculation of expressed juice has not been demonstrated. No transmission through seeds from diseased rice plants. No soil transmission.

Literature: Agati et al., Philippine Jour. Agr., 12, 1941, 197-210; Fukushima, Trans. Sapporo Nat. Hist. Soc., 12, 1931, 35-41; Proc. Imp. Acad., Tokyo, 3, 1933, 457-460; Jour. Fac. Agr. Hokkaido Imp. Univ., 37, 1934, 41-164; Trans. Sapporo Nat. Hist. Soc., 13, 1934, 162-166; Proc. Imp. Acad., Tokyo, 11, 1935, 301-303; 13, 1937, 323-331; 15, 1939, 142-145; Jour. Fac. Agr. Hokkaido Imp. Univ., 45, 1940, 83-154; Katsura, Phytopath.,

Transmission: By leafhopper, *Cicadula bimaculata* Evans (CICADELLIDAE) Literature: Schindler, Jour. Austral. Inst. Agr. Sci., 8, 1942, 35-37.

Genus VI. *Fractilinea* McKinney.

(Jour. Washington Acad. Sci., 34, 1944, 148.)

Viruses of the Stripe-Disease Group; hosts grasses; insect vectors, cicadellid and fulgorid leafhoppers Generic name from Latin, meaning interrupted and line.

The type species is *Fractilinea maidis* (Holmes) McKinney.

Key to the species of genus *Fractilinea*.

I. Vectors, cicadellid leafhoppers.

1. *Fractilinea maidis*.
2. *Fractilinea oryzae*.
3. *Fractilinea tritici*.
4. *Fractilinea quarla*.

II. Vectors, fulgorid leafhoppers

5. *Fractilinea zeae*.
6. *Fractilinea arcanae*.

1. *Fractilinea maidis* (Holmes) McKinney (*Marmor maidis* Holmes, Handb. Phytopath. Viruses, 1939, 56, *Fractilinea maidis* McKinney, Jour. Washington Acad. Sci., 34, 1944, 149) From New Latin *mays*, corn (i.e. maize)

Common name: Maize-streak virus

Hosts: GRAMINEAE—*Zea mays* L., corn (maize); *Digitaria horizontalis* Willd., *Eleusine indica* Gaert., *Saccharum officinarum* L., sugar cane.

Geographical distribution: Africa

Induced disease. In corn, pale spots at base of young leaf, followed by chlorotic spotting and streaking of subsequently formed leaves. Virus moves rapidly (up to 40 cm in 2 hours at 30° C) after introduction into host plant by insect. More virus in chlorotic spots than in green areas of affected leaves

Transmission: By leafhoppers, *Cicadulina* (= *Stalctutha*) *mbila* (Naude), *C. zeae* China, and *C. storeyi* China (CICADELLIDAE). In *C. mbila* ability to transmit this virus is controlled by a sex-linked dominant gene, active male (AX) (Y), inactive male (ax) (Y), inactive female (ax) (ax), active female (AX) (AX) or (AX) (ax). Inactive individuals ingest virus when feeding, but can become infective only if the intestine

is wounded purposely or accidentally. If inoculated artificially by introducing virus into blood, both active and inactive insects become infective. Incubation period, 6 to 12 hours at 30° C. Young not infected through the egg. Infective leafhopper cannot transmit virus unless feeding puncture exceeds a minimum period, about 5 minutes in duration. This virus has not been transmitted to its plant hosts by inoculation of expressed juices.

Filterability. At pH 6, passes Chamberland L<sub>1</sub> and L<sub>2</sub>, Berkefeld V and N, filters, retained by Seitz E K filter disc.

Literature: Storey, Ann. Appl. Biol., 12, 1925, 422-439; 15, 1928, 1-25; 19, 1932, 1-5, Proc. Roy. Soc., B, 115, 1932, 46-60, 115, 1933, 463-485; 125, 1938, 455-477; Ann. Appl. Biol., 21, 1934, 588-589; 24, 1937, 87-94, East Afr. Agr. Jour., 1, 1938, 471-475, Storey and McClean, Ann. Appl. Biol., 17, 1930, 691-719

Strains: Two strains that differ radically from the type, var. *typicum* II. (loc. cit., 56), have been given varietal names, as follows

1. *Fractilinea maidis* var. *sacchari* II. (loc. cit., 57) From New Latin *Saccharum*, generic name of sugar cane. Common name: Cane-streak strain of

sect is usually between 11 and 29 days, although shorter periods have been demonstrated in a few cases. Virus may persist in the insect host until death, but may become exhausted earlier. Not by aphid, *Aphis maidis* Fitch (*APHIDIDAE*). Not by inoculation of expressed juice

Literature: Briton-Jones, Trop. Agr., 10, 1933, 119-122; Carter, Ann. Ent. Soc. Am., 34, 1941, 551-556; Kunkel, Bull. Hawaiian Sugar Planters' Assoc., Bot. Ser., 3, 1921, 44-57; 1924, 108-114; Hawaiian Planters' Rec., 26, 1922, 58-64; Phytopath., 17, 1927, 41 (Abst.); Stahl, Trop. Pl. Res. Found., Bull. 7, 1927; Storey, Rept. of Plant Pathologist, Amani Agr. Res. Station, 4th Ann. Rept., 1931-32, pp 8-13

6. *Fractilinea avenae* McKinney (Jour. Washington Acad. Sci., 34, 1944, 327.) From Latin *avena*, oats

Common name: Pupation-disease virus.

Hosts: *GRAMINEAE*—*Avena sativa* L., oat; *Triticum aestivum* L., wheat;

*Echinochloa crusgalli* Beauv.; *Setaria viridis*; rarely, *Agropyron repens* (L.) Beauv. and *Bromus inermis* Leyss. Experimentally, also *Hordeum vulgare* L., barley; *Panicum miliaceum* L., millet; *Oryza sativa* L., rice; *Secale cereale* L., rye; *Zea mays* L., corn (maize).

Geographical distribution: West Siberia.

Induced disease: In oat, chlorotic mottling, profuse development of shoots, proliferation of flowers with change to leaf-like structures. Protein crystals in affected cells have been regarded as accumulated virus.

Transmission: By leafhopper, *Delphax striatella* Fallan (*FULGORIDAE*), especially first and second instar nymphs; fifth instar nearly immune to infection. Incubation period, 6 days or more. Virus overwinters in insect as well as in plants. Not transmitted from an infected leafhopper to its progeny. Not through soil. Not through seeds from infected plants.

Literature: Sukhov et al., Compt. rend. Acad. Sci., U. R. S. S., 20, 1938, 745-748, 26, 1940, 479-482, 483-486.

26, 1936, 887-895; Takata, Jour. Japan Agr. Soc., 171, 1895, 1-4, 172, 1896, 13-32 (Takata's papers, in Japanese, constitute the first published record of transmission by an insect of a virus causing disease in a plant, the leafhopper *Deltocephalus dorsalis* Motsch. transmitting dwarf-disease virus to rice; see Fukushi, 1937, cited above).

3 *Fractilinea tritici* McKinney. (Jour. Washington Acad. Sci., 34, 1944, 327) From Latin *tritium*, wheat

Common name. Winter-wheat mosaic virus

Hosts GRAMINEAE—*Triticum aestivum* L., wheat; *Scaevola cereale* L., rye, *Avena byzantina*; *A. sativa* L., wild oat, *A. sativa* L., oat, *Hordeum vulgare* L., barley.

Geographical distribution Union of Soviet Socialist Republics.

Induced disease. In winter wheat and rye, chlorotic mottling; profuse branching. In winter wheat, phloem necrosis, chloroplasts few, small; vacuolate inclusions in cells; nuclei enlarged and with extra nucleoli, no protein crystals of the pupation-disease type in affected cells. In spring wheat, barley, and oats, chlorotic mottling without profuse branching, no proliferation of flowers, but grain is rarely formed, most infected plants dying before this stage of growth.

Transmission: By leafhopper, *Deltocephalus striatus* L. (CICADELLIDAE), with incubation period of 15 to 18 days. Not by inoculation of expressed juice. Not through soil.

Literature. Zakhurilo and Sitnikova, Compt. rend. Acad. Sci. U. R. S. S., 25, 1939, 798-801; 26, 1940, 474-478, 29, 1940, 429-432, Proc. Lenin Acad. Agr. Sci., U. R. S. S., 6, 1941, 27-29 (Rev. Appl. Myc., 19, 1940, 268; 20, 1941, 157, 396, 22, 1943, 59).

4 *Fractilinea quarta* (Holmes) comb. nov. (*Marmor quartum* Holmes, loc. cit., 65) From Latin *quartus*, fourth

Common name: Sugar-cane chlorotic-streak virus or fourth-disease virus.

Host: GRAMINEAE—*Saccharum officinarum* L., sugar cane.

Geographical distribution. Java, Queensland, Hawaii, Puerto Rico, Colombia, United States (Louisiana).

Induced disease. In sugar cane, reduction of growth rate; wilting at midday; long, narrow, longitudinal streaks, of creamy or white color, in the leaves. Streaks 1/16 to 3/16 inches wide, generally less than 1 foot long, fragmenting.

Transmission. By leafhopper, *Draculacephala portola* Ball (CICADELLIDAE). Not demonstrated by inoculation of expressed juice.

Thermal inactivation: In cuttings, at 52° C in less than 20 minutes.

Literature: Abbott, Phytopath., 28, 1938, 855-857; Sugar Bull., 16, 1938, 3-4; Abbott and Ingram, Phytopath., 32, 1942, 99-100; Bell, Queensland Agr. Jour., 40, 1933, 460-461; Martin, Hawaiian Planters' Rec., 34, 1930, 375-378; Hawaiian Sugar Planters' Assoc. Proc., 63, 1931, 21-35.

5 *Fractilinea zea* (Holmes) comb. nov. (*Marmor zea* Holmes, loc. cit., 50.) From New Latin *zea*, generic name for corn (maize), from Latin *zea*, a kind of grain.

Common name. Maize-stripe virus.

Host. GRAMINEAE—*Zea mays* L., corn (maize).

Insusceptible species GRAMINEAE—*Saccharum officinarum* L., sugar cane.

Geographical distribution. Hawaii, Tanganyika, Mauritius, Trinidad, Cuba. Not in United States.

Induced disease. In corn (maize), at first few, elongated, chlorotic lesions near base of young leaf, later enlarging and fusing to form continuous stripes. Subsequently formed leaves banded and striped variously. Vacuolate intracellular inclusions in cells of affected areas.

Transmission. By leafhopper, *Percnurus maidis* (Ashm.) (FULGORIDAE), the incubation period in this in-

- I. Found in nature principally in solanaceous plants; *Cucurbitaceae* insusceptible. Chlorotic mottling in some hosts, necrotic lesions in others as result of experimental infection. Suspensions show anisotropy of flow.
  1. *Marmor tabaci*.
  2. *Marmor constans*.
- II. Found in nature only in cucurbitaceous plants; *Solanaceae* insusceptible. Only mottling as result of experimental infection. Suspensions show marked anisotropy of flow.
  3. *Marmor strictum*.
- III. Found only in leguminous plants. Chlorotic lesions in some varieties of the common snap-bean plant, necrotic lesions in others, as a result of experimental infection.
  4. *Marmor laesiofaciens*.
- IV. Found in greenhouses confined to roots and lower parts of plants. Only necrotic lesions as result of experimental infection. Suspensions do not show anisotropy of flow.
  5. *Marmor lethale*.
- V. Found in tomato and experimentally transmissible to a number of species of plants in this and other families. Resembling the preceding in a number of physical characteristics, including failure to show anisotropy of flow.
  - 5a. *Marmor dodecahedron*.

1 *Marmor tabaci* Holmes (Holmes, Handb. Phytopath. Viruses, 1939, 17; *Musivum tabaci* Valicau, Phytopath., 30, 1940, 822; *Phytovirus nicomosaicum* Thornberry, Phytopath., 31, 1941, 23.) From New Latin *Tabacum*, early generic name for tobacco

Common names: Tobacco-mosaic virus, tomato-mosaic virus.

Hosts. *SOLANACEAE*—*Nicotiana tabacum* L., tobacco; *Lycopersicon esculentum* Mill., tomato, and *Capsicum frutescens* L., garden pepper, among crop plants; nearly all, if not all, solanaceous plants can be infected, although in some the virus remains localized at or near the site of inoculation. *PLANTAGINACEAE*—A strain of this virus has been found in nature infecting *Plantago lanceolata* L., ribgrass, *P. major* L. and *P. rugelii* Dene., common broad-leaved plantains. Experimental hosts are widely distributed through many related families of plants.

Geographical distribution: World-wide.

Induced disease: In most varieties of tobacco, yellowish-green primary lesions, followed by clearing of veins, distortion and greenish-yellow mottling of newly formed leaves. In Ambalema tobacco,

no symptoms, virus being restricted to inoculated leaves or those nearby. Strains of tobacco showing necrotic effects have been produced recently. In tomato, no obvious primary lesions, systemic disease characterized by greenish-yellow mottling of foliage, moderate distortion of leaf shape, and a reduction of fruit yield not exceeding 50 per cent. If some strain of potato-mottle virus (*Marmor dubium*) is also present, a more severe disease is induced; this is known as double-virus streak, and is characterized by systemic necrosis. In most varieties of garden pepper, yellowish primary lesions followed by systemic chlorotic mottling. In the Tabasco pepper and its recent derivatives, recovery by abscission of inoculated leaf, after localization of virus in necrotic primary lesions. Vacuolate intracellular inclusions are found in chlorotic tissues of all hosts that show distinct chlorotic mottling.

Transmission: By slight abrasive contacts. By inoculation of expressed juice. To some extent by the aphids, *Myzus pseudosolani* Theob., *M. circumflexus* (Buckt.), *Macrosiphum solanifolii* Ashm., and *Myzus persicae* (Sulz.) (*APHIDI-DAE*). By grafting. Through soil.

## FAMILY MARMORACEAE

FAMILY II. MARMORACEAE HOLMES EMEND  
(Handb. Phytopath. Viruses, 1939, 16.)

Viruses of the Mosaic Group, inducing diseases usually characterized by persistent chlorotic or necrotic spotting, and often by mottling. The family is here extended to include several small groups of viruses, formerly assigned independent family rank, but sharing a tendency to aphid transmission, so far as known, and inducing diseases characterized by abnormal growth habit, thickening and rolling of leaves, or dwarfing, traits not incompatible with the characters of the present group. Should any one of these small groups become the center of a large assemblage of new viruses in the future, separate familial status for it might again be advantageous. In the combined group, ing here used, specific vectors, so far as known, are aphids (APHIDIDAE).

Key to the genera of family Marmoraceae.

- I Viruses of the Typical Mosaic-Disease Group.  
Genus I *Marmor*, p. 1163
- II Viruses of the Spindle-Tuber Group  
Genus II *Acrogenus*, p. 1202
- III Viruses of the Leaf-Roll Group  
Genus III. *Corium*, p. 1203
- IV Viruses of the Dwarf-Disease Group  
Genus IV *Nanus*, p. 1206
- V Viruses of the Rough-Bark Group  
Genus V *Rimocortius*, p. 1208
- VI Viruses of the Symptomless Group.  
Genus VI *Adelonosus*, p. 1211

Genus I *Marmor* Holmes

(Loc. cit., 16)

Viruses inducing typical mosaic diseases in various plants Generic name from Latin *marmor*, a mottled substance  
The type species is *Marmor tabaci* Holmes

Key to the groups within genus *Marmor*.

- A Relatively resistant to heat inactivation, usually requiring more than 10 minutes at 85 to 90° C for complete inactivation  
1 Tobacco-Mosaic Virus Group
- B Relatively susceptible to heat inactivation  
85 to 90° C for complete inactivation  
a Replacing potato-veinbanding virus in mixed infections  
2 Tobacco-Etch Virus Group
- aa Not replacing potato-veinbanding virus in mixed infections  
3 Cucumber Mosaic Virus Group.
- C Many additional species cannot yet be grouped into definite subdivisions of the genus, they constitute a residual or  
4 Miscellaneous Mosaic-Virus Group.

Key to the species of the Tobacco Mosaic Virus Group

Viruses relatively resistant to heat inactivation, requiring in most cases more than 10 minutes at 85 to 90° C for complete inactivation Insect vectors as yet unknown under natural conditions

Gelatin colonies: Smooth, soft, flat, spreading, entire, yellowish-green.

Gelatin stab: Growth along stab. Liquefaction with yellowish-white sediment.

Agar colonies: Circular, raised, smooth, amorphous, entire.

Agar slant: Yellowish-white, moist, glistening, becoming light green-fluorescent.

Broth: Turbid, with yellowish-white sediment.

Litmus milk: Flocculent precipitation. Slow peptonization with yellow serum. Alkaline.

Potato: Dirty yellow to olive, moist, glistening, entire.

Indole is formed.

Nitrates reduced to nitrites and ammonia. No gas formed

Aerobic, facultative

Optimum temperature 22°C.

Source: Isolated from beer

14. *Pseudomonas septica* Bergey et al. (*Bacillus fluorescens septicus* Stutzer and Wsorrow, Cent. f. Bakt., II Abt., 71, 1927, 113; Bergey et al., Manual, 3rd ed., 1930, 169.) From Greek, *septikos*, putrefactive, septic

Rods: 0.6 to 0.8 by 0.8 to 2.0 microns, occurring singly. Motile with a polar flagellum. Gram-negative.

Gelatin stab: Infundibuliform liquefaction.

Agar colonies: Circular with opalescent center and transparent periphery

Agar slant: Moderate, undulate margin.

Broth: Turbid with fragile pellicle, greenish in upper portion.

Litmus milk: Alkaline, coagulated

Blood serum not liquefied

Acid from glucose.

Aerobic, facultative.

Optimum temperature 20°C.

Habitat: Disease of caterpillars

15. *Pseudomonas boreopolis* Gray and Thornton (Gray and Thornton, Cent. f. Bakt., II Abt., 73, 1928, 74.) From

Greek, *boreas*, the North wind; *polis*, city; M. L. North City.

Rods: 0.5 to 1.0 by 2.0 to 3.0 microns, occurring singly and in pairs. Motile with one to five polar flagella. Gram-negative.

Gelatin colonies: Liquefied.

Gelatin stab: Liquefied. Medium red-dened.

Agar colonies: Circular or amoeboid, white to buff, flat to convex, smooth, glistening, translucent border.

Agar slant: Filiform, whitish, raised, smooth, glistening, fluorescent.

Broth: Turbid.

Nitrates reduced to nitrites.

Starch not hydrolyzed.

Acid produced from glucose.

Attacks naphthalene.

Aerobic, facultative.

Optimum temperature 20° to 25°C.

Habitat: Soil.

16. *Pseudomonas smaragdina* Migula. (*Bacillus smaragdinus foetidus* Reiman, Inaug. Dissertation, Würzburg, 1887; Migula, Syst. d. Bakt., 2, 1900, 890.) From Greek, *smaragdinas*, green like the *smaragdus*, the emerald.

Small rods, occurring singly. Non-motile. Gram-negative.

Gelatin colonies: Small, convex, irregular, whitish with greenish shimmer.

Gelatin stab: Slight surface growth. Infundibuliform liquefaction. The liquefied medium becomes light emerald green in color.

Agar colonies: Small, brownish-yellow, convex.

Agar slant: Abundant growth with greenish fluorescence.

Broth: Turbid.

Litmus milk: Not coagulated.

Potato: Dark brown, becoming chocolate brown.

Indole not formed.

Nitrates not reduced.

The cultures give off an odor resembling jasmine.

Aerobic, facultative.

Through dodder, *Cuscuta campestris* Yunker (*CONVOLVULACEAE*), without infecting this plant vector. Not through pollen from diseased plants. Not through seeds from diseased tobacco; seed transmission has been reported in the case of recently ripened seeds from diseased tomato.

**Serological relationships.** Precipitin test gives cross reactions between all known strains, except those characterized by failure to spread systemically in tobacco. No cross reactions with other viruses except weakly with cucurbit-mosaic virus (*Marmor astrictum*). Type and other strains of tobacco-mosaic virus gave cross reactions in complement-fixation and neutralization tests.

**Immunological relationships.** Plant protection tests, particularly in *Nicotiana sylvestris* Spreng and Comes, have demonstrated that tissues invaded by any strain of this virus are immune to subsequent infection by the tomato aucubamosaic strain of tobacco-mosaic virus, indicating a group relationship not shared by other viruses, such as cucumber-mosaic virus or tobacco ring-spot virus.

**Thermal inactivation.** At 88 to 93° C in 10 minutes, at 86 to 92° C in 30 minutes.

**Filterability.** Tobacco mosaic virus was the first virus shown to be filterable, by Iwanowski in 1892, its filterability was confirmed and interpreted by Beijerinck in 1898.

**Other properties.** The ultimate particles of tobacco mosaic virus have been shown to be rod-shaped and isotropic, sometimes associated in pairs, end to end. Under proper conditions, thread-like paracrystals are formed. Specific gravity has been determined as about 1.37, refractive index as about 1.6. Isoelectric point between pH 3.2 and 3.5. Suspensions in media of lower refractive indices show anisotropy of flow. Sedimentation constants, at 20° C,  $157 \times 10^{-11}$  cm per sec. per dyne at infinite dilution for unaggregated virus and  $216 \times 10^{-11}$  cm per sec. per dyne for associated particles. The computed average length of the virus

unit is about 272 millimicrons; diameter, 13.8 millimicrons. Electron micrographs show that characteristic particles are rod-like, between 10 and 20 millimicrons in width, variable in length, but in some preparations averaging 270 millimicrons in length for single units, 405 to 540 millimicrons in length for associated pairs; X-ray measurements in air-dry gel show width  $15.20 \pm 0.05$  millimicrons. Solutions stronger than about 1.3 per cent separate into layers, the lower spontaneously doubly refracting and more concentrated than the upper. At concentrations of electrolytes somewhat less than are required to precipitate the virus as fibres or needle-shaped paracrystals, the solutions form clear gels that become fluid on shaking or diluting (at pH 7 and 30° C). The virus is destroyed by high-frequency sound radiation, by pressures between 6000 and 8000 kilograms per square centimeter, and by hydrogen-ion concentrations above pH 11 or below pH 1. It is relatively stable between pH 2 and pH 8. It is rapidly broken down in 6 M urea solutions, in the presence of salts, to low-molecular-weight components devoid of activity. Analysis of purified virus: carbon 47.7 per cent, hydrogen 7.35 per cent, nitrogen 15.9 per cent, sulfur 0.21 per cent, phosphorus 0.60 per cent, lipid 0.0 per cent, carbohydrate 1.6 to 2.0 per cent. A revised estimate of the sulfur content is 0.20 per cent, probably all in cysteine, no methionine has been detected in the typical variety of this virus. The percentages of the following substances in the virus are: tyrosine 3.9, tryptophane 1.5, proline 4.6, arginine 9.0, phenylalanine 6.0, serine 6.4, threonine 5.3, cysteine 0.68, alanine 2.4, aspartic acid 2.6, glutamic acid 5.3, leucine 6.1, valine 3.9, nucleic acid 5.8, and amide nitrogen 1.9, collectively accounting for about 68 per cent of the total weight. Virus formation ceases in infected host tissues immersed in 0.0002 molar sodium cyanide solution, beginning again after removal of cyanide.

**Literature:** The literature dealing with tobacco-mosaic virus is too voluminous to permit citation of more than a few representative publications. Allard, U. S. Dept. Agr., Bull. 40, 1914; Bawden and Pirie, Proc. Roy. Soc. London, Ser. B., 125, 1937, 274-320; Beale, Jour. Exp. Med., 54, 1931, 463-473; Beijerinck, Verhandl. Konink. Akad. Wetenschappen te Amsterdam, II, 6, 1898, 3-22; Grant, Phytopath., 24, 1934, 311-336; Hoggan, Jour. Agr. Res., 49, 1954, 1135-1142; Iwanowski, Bull. Acad. Imp. Sci. St. Petersburg, Ser. 4, 5, 1892, 67-70; Jensen, Phytopath., 23, 1933, 964-974; Johnson, Science, 64, 1926, 210; Kausche et al., Naturwiss., 27, 1939, 292-299; Knight, Jour. Biol. Chem., 147, 1943, 663-666; Kunkel, Phytopath., 24, 1934, 437-466; Lauffer, Jour. Am. Chem. Soc., 66, 1944, 1188-1194; Price, Phytopath., 25, 1933, 749-769; Stanley, Phytopath., 26, 1936, 303-320; Takahashi and Rawlins, Proc. Soc. Exp. Biol. and Med., 50, 1932, 155-157; Vallean and Johnson, Kentucky Agr. Exp. Sta., Bull. 376, 1937; Vinson, Science, 66, 1927, 357-358; Woods, Science, 91, 1940, 295-296.

**Strains:** A great number of variant strains have been isolated both experimentally and from plants infected in nature. These usually share with the type variety most of the fundamental properties, particle size, especially width, stability at relatively high temperatures, longevity in storage, some common antigens. The following have been distinguished from the type, var. *vulgare* H. (loc. cit., 17), by varietal names:

1a. *Marmor tabaci* var. *aucuba* H. (loc. cit., 20). A group of isolates producing necrotic local lesions in inoculated leaves of *Nicotiana sylvestris* Speng. and Comes; useful in identifying many other strains of this virus which on prior application protect the tissues of this plant from the necrotic effects of *aucuba*-type strains (Smith, Ann. Appl. Biol., 18, 1931, 471-493; Kunkel, Phytopath., 24, 1934, 437-466).

1b. *Marmor tabaci* var. *deformans* H. (loc. cit., 22). Producing exceptionally severe malformation of tomato foliage. (Ainsworth, Ann. Appl. Biol., 24, 1937, 545-556).

1c. *Marmor tabaci* var. *canadense* H. (loc. cit., 23). Producing a necrotic type of streak disease in tomatoes (Jarrett, Ann. Appl. Biol., 17, 1930, 248-259).

1d. *Marmor tabaci* var. *lethale* H. (loc. cit., 24). Producing spreading necrotic lesions in tobacco and tomato under experimental conditions (Jensen, Phytopath., 27, 1937, 69-84; Norval, Phytopath. 28, 1938, 675-692).

1e. *Marmor tabaci* var. *plantaginis* H. (Phytopath., 31, 1911, 1037). Specially adapted in nature for systemic spread in species of *Plantago*. This variety contains histidine (0.55 per cent) and methionine (2 per cent) not found in the type of the species.

1f. *Marmor tabaci* var. *obscurum* H. (Handb. Phytopath. Viruses, 1939, 25). Systemic in tobacco without producing obvious disease under experimental conditions (Holmes, Phytopath., 24, 1934, 845-873; 26, 1936, 896-904; Jensen, Phytopath., 27, 1937, 69-84).

1g. *Marmor tabaci* var. *immobile* H. (loc. cit., 26). Produces chlorotic primary lesions in experimentally infected tobacco, but rarely becomes systemic. (Jensen, Phytopath., 23, 1933, 964-977; 27, 1937, 69-84).

1h. *Marmor tabaci* var. *artum* H. (loc. cit., 27). Necrotic lesions experimentally induced in *Nicotiana glutinosa* L. (*SOLANACEAE*) are much smaller than those of the type variety (Jensen, Phytopath., 27, 1937, 69-84).

1i. *Marmor tabaci* var. *siccans* Doolittle and Beecher. (Phytopath., 32, 1942, 991). Causing necrosis and shriveling of tomato foliage.

2. *Marmor constans* McKiuney (Jour. Washington Acad. Sci., 34, 1944, 326.) From Latin *constans*, fixed.

Common name. Tobacco mild dark-green mosaic virus

Hosts. *SOLANACEAE*—*Nicotiana glauca* R. Grub., tree tobacco

Insusceptible species. *SOLANACEAE*—*Lycopersicon esculentum* Mill., tomato

*CUCURBITACEAE*—*Cucumis sativus* L., cucumber

Geographical distribution. Islands of Grand Canary and Teneriffe

Induced disease. In *Nicotiana glauca*, systemic chlorotic mottling

Transmission. By inoculation of expressed juice. No insect vector is known

Thermal inactivation. At about 86°C in 10 minutes

Literature. McKinney, Jour. Agr. Res. 39, 1929, 557-578, Am. Jour. Bot. 28, 1941, 770-778, Peterson and McKinney, Phytopath., 28, 1938, 329-342, Thornberry and McKinney, *ibid.* 29, 1939, 250-260

3. *Marmor astrictum* Holmes (Holmes, Handb. Phytopath. Viruses, 1939, 27; *Musurum astrictum* Valleron, Phytopath., 50, 1940, 823) From Latin *astrictus*, limited, in reference to host range

Common names. Cucurbit-mosaic virus, English cucumber mosaic virus

Hosts. *CUCURBITACEAE*—*Cucumis sativus* L., cucumber, *C. anguria* L., gherkin, *C. melo* L., melon, *Citrullus vulgaris* Schrad., watermelon; only cucurbitaceous plants have appeared to be susceptible thus far.

Insusceptible species. All tested solanaceous species

*CUCURBITACEAE*—*Syrionia dioica* L.; *Cucurbita pepo* L., vegetable marrow. *LEGUMINOSAE*—*Phaseolus vulgaris* L. var. Golden Cluster

Geographical distribution. England

Induced disease. In cucumber, clearing of veins and crumpling in young leaves, followed by a green mosaic mottling, with

blistering and distortion of newly formed leaves. Plant stunted. Fruit unmarked or slightly mottled. Diseased plants less obviously affected during winter months.

Transmission. By inoculation of expressed juice. No insect vector is known.

Serological relationships. Weak cross-precipitin reactions and full cross-neutralization reactions with tobacco-mosaic virus (*Marmor tabaci*). Two common antigens postulated. Preparations of virus that have been inactivated by treatment with nitrous acid or X-rays are still antigenic.

Thermal inactivation. At 80 to 90°C in 10 minutes.

Filterability. Passes Pasteur-Chamberland filters  $L_1$  to  $L_2$ , and membranes of 150 millimicrons average pore diameter.

Other properties. Virus, infectious in dilution of  $10^{-10}$ , is present to the extent of 0.2 to 0.3 gram per liter of juice from diseased plants. Preparations show sheen and anisotropy of flow, indicating rod-shaped particles. Solutions stronger than 2.5 per cent separate into 2 layers at room temperature, the lower being the more concentrated and birefringent. Precipitates with ammonium sulfate show needle-shaped paracrystals. Sedimentation constants  $S_{20}^0 = 173 \times 10^{-13}$  cm. sec.<sup>-1</sup> dyne<sup>-1</sup> and about  $200 \times 10^{-13}$  cm. sec.<sup>-1</sup> dyne<sup>-1</sup>. Virus withstands drying without inactivation but with partial loss of ability to show anisotropy of flow and with reduction of serological activity to about half. Tryptophane content 1.4 per cent, phenylalanine 10.2 per cent, the first lower and the second higher than in tobacco-mosaic virus.

Literature. Ainsworth, Ann. Appl. Biol., 22, 1935, 55-67, Rowden and Price, Nature, 129, 1937, 546-547; Brit. Jour. Exp. Path., 18, 1937, 275-291; Knight, Arch. Virol., 2, 1942, 260-267; Knight and Stanley, Jour. Biol. Chem., 141, 1941, 29-38, 141, 1941, 39-49; Price, Am. Jour. Bot., 27, 1940, 530-541; Price and Wyeckoff, Nature, 141, 1938, 685.

Strains: A distinctive strain has been distinguished from the type, var. *chlorogenuis* H. (*loc. cit.*, 27), by the varietal name:

3a. *Marmor astrictum* var. *aucuba* H. (*loc. cit.*, 29). Differing from the type of this species by inducing a yellow-mottling, rather than a green-mottling, mosaic in cucumber (Ainsworth, *Ann. Appl. Biol.*, 22, 1935, 55-67).

4. *Marmor laesiofaciens* Zaumeyer and Harter. (*Jour. Agr. Res.*, 67, 1943, 305.) From Latin *laesio*, substantive from *laedere*, to injure, and participle from *facere*, to make.

Common name: Bean-mosaic virus 4; southern bean mosaic virus 1.

Hosts: **LEGUMINOSAE**—*Phaseolus vulgaris* L., bean. Experimentally, also *Phaseolus lunatus* L., sieva bean; *Soja max* Piper var. Virginia, Virginia soy bean.

Insusceptible species: All tested species in families other than the **LEGUMINOSAE**.

Geographical distribution: United States (Louisiana).

Induced disease: In bean, systemic chlorotic mottling in some varieties, localized necrosis in others; in a few varieties, systemic necrosis. In mottling-type varieties, chlorotic mottling of foliage; pods marked by dark green blotches or shiny areas, slightly malformed, short, frequently curled at end. In necrotic-type varieties with localized response, bearing a dominant gene lacking in mottling-type varieties, reddish necrotic lesions at the site of inoculation; no evidence of systemic spread of virus. In varieties showing systemic necrosis, pinpoint or slightly larger necrotic primary lesions with veinal necrosis of inoculated leaf; systemic veinal necrosis, distortion and curling of affected leaves, drooping at the pulvini, stem and petiole streak; eventual death of plant.

Transmission: By inoculation of expressed juice. Through seeds from infected plants.

Serological relationships: Not demonstrated.

Immunological relationships: Previous infection with bean-mosaic virus, *Marmor phaseoli*, does not protect against infection with this virus.

Thermal inactivation: At 90 to 95° C, time not stated, probably 10 minutes.

Other properties: Withstands dilution of 1:100,000 at 18° C.

34, 1944, 510-512; *Jour. Agr. Res.*, 67, 1943, 295-300, 305-323.

Strains: A strain differing from the type has been given the varietal name:

4a. *Marmor laesiofaciens* var. *minus* Zaumeyer and Harter. (*Jour. Agr. Res.*, 67, 1943, 305.) From Latin *minor*, lesser. Differing from the type by inducing formation of slightly less diffuse and spreading lesions in necrotic-type bean leaves; also by inducing milder early symptoms and more severe late symptoms in mottling-type beans. Passes through

5. *Marmor lethale* H. (*loc. cit.*, 86).

*us.*  
*ina*  
*N.*  
*tabacum* L., tobacco, *N. glauca* Weinm.; *Lycopersicon esculentum* Mill., tomato; *Solanum nigrum* L. **COMPOSITAE**—*Aster*. **GERANIACEAE**—*Pelargonium hortorum* Bailey. **LEGUMINOSAE**—*Phaseolus vulgaris* L., bean. Confined to roots of these natural hosts except in the cases of *Nicotiana tabacum* and *N. glutinosa* in which lower leaves are sometimes invaded; necrotic lesions along midrib and larger veins in these. No obvious manifestations of disease in infected roots. Experimentally to plants in many families with production of localized necrotic lesions only.

Geographical distribution: England, Scotland, Australia. This virus has been found only in greenhouses.

Induced disease: In tobacco, necrosis of midrib and larger veins of first-developed pair of leaves, between November and February. Virus also in roots of many healthy-looking plants throughout the year. Upon artificial inoculation of foliage, numerous small brown necrotic local lesions are produced. Yield of virus from infected plant 0.02 mg per cc of expressed juice, on the average.

Transmission. By contamination of soil with virus. No insect vector is known. Experimentally, by inoculation of expressed juice.

Serological reactions: Precipitates with homologous antiserum. No cross reaction with tomato bushy-stunt or tobacco-mosaic viruses.

Immunological relationships: Protection tests show lack of relationship to tobacco-mosaic virus, tobacco-ringspot virus, tomato-ringspot virus, cucumber-mosaic virus, and the severe-etch strain of tobacco-etch virus.

Thermal inactivation: At 90 to 92° C in 10 minutes.

Filterability: Average particle diameter 20 to 30 millimicrons as determined by filtration through Gradocol membranes; other reports give diameter as 13 to 20 millimicrons by filtration (14 to 19 millimicrons by radiation experiments, about 20 millimicrons from electron micrographs).

Other properties: Infectious after storage for months in dried leaves and after storage for half a year in absolute ethyl alcohol at room temperature. Specific gravity 1.3. More soluble in ammonium sulfate solutions at 0° C than at room temperature. Composition. Carbon 41.8 to 45.3 per cent, nitrogen 15.5 to 16.5 per cent, hydrogen 6.5 to 7.0 per cent, phosphorus 1.4 to 1.7 per cent, sulfur 1.3 to 2.0 per cent, carbohydrate 7.0 to 9.0 per cent, ash 5.4 to 7.0 per cent (3 to 5 per cent after prolonged dialysis at pH 3). Nucleic acid of the ribose type has been

isolated. No anisotropy of flow in solution but crystals are birefringent, showing sharp extinctions parallel to, and at right angles to, the plane of the crystal when examined edge-on in a polarizing microscope. Sedimentation constant,  $S_{20}^0 = 112 \times 10^{-13}$ ; in other preparations a crystalline component with sedimentation constant  $130 \times 10^{-13}$  and an amorphous component with sedimentation constant  $58 \times 10^{-13}$  have been reported, as well as small amounts of a substance with sedimentation constant  $220 \times 10^{-13}$ .

Strains: Isolates of tobacco-necrosis virus serologically distinct but not otherwise different from each other appear to imply the existence of several strains of this virus, or of a closely related group of viruses, in England.

Literature: Rawden, Brit. Jour. Exp. Path., 22, 1911, 59-70; Rawden et al., *ibid.*, 23, 1912, 314-328; Cohen, Proc. Soc. Exp. Biol. and Med., 48, 1911, 163-167; Lea, Nature, 146, 1910, 137-138; Pirie et al., Parasitol., 30, 1938, 513-551; Price, Am. Jour. Bot., 25, 1938, 603-612; Am. Jour. Bot., 27, 1910, 530-511; Arch. Virus, 1, 1910, 373-386; Price and Wyckoff, Phytopath., 23, 1933, 83-91; Smith, Parasitol., 29, 1937, 70-85; 29, 1937, 86-95; Smith and Bald, Parasitol., 27, 1935, 231-215; Smith and MacClement, Parasitol., 32, 1910, 320-332.

5a. Marmor dodecahedron H. (*loc. cit.*, 30). From Greek *dōdelahedron*, dodecahedron.

Common name. Tomato bushy-stunt virus.

Hosts: SOLANACEAE—*Lycopersicon esculentum* Mill., tomato. Experimentally, also SOLANACEAE—*Datura stramonium* L.; *Nicotiana glutinosa* L.; *N. langsdorffii* Weinm.; *N. tabacum* L., tobacco; *Solanum nigrum* L. LEGUMINOSAE—*Phaseolus vulgaris* L., bean, *Vigna sinensis* (L.) Endl., cowpea. COMPOSITAE—*Zinnia elegans* Jacq., zinnia.

Geographical distribution: British Isles.

**Induced disease:** In tomato, some primary lesions necrotic, ring-like or spot-like, others masked, or disclosed only by chlorophyll retention in yellowing leaves. In young plants, systemic necrotic lesions may cause death; in older plants, growth ceases, young leaves become pale yellow; growing points may die, inducing growth of axillary buds to produce a bushy top; older leaves become yellowed and show some purple coloration. In White Burley tobacco, local necrosis only, lesions small, red at first, then white. In cowpea, reddish necrotic primary lesions only.

**Transmission:** By inoculation of expressed juice. Through dodder, *Cuscuta campestris* Yuncker (*CONVOLVULACEAE*). Not through seeds of diseased plants. No insect vector is known.

**Serological relationships:** A specific antiserum, prepared by a single intravenous injection of rabbits with 2 mg of purified virus, gives granular, compact precipitates, serving for quantitative estimation of this virus, antiserum being used at dilutions of 1:200 or 1:800, virus at dilutions to  $10^{-6}$ .

**Immunological relationships.** Will infect plants previously invaded by tobacco-mosaic virus, tomato spotted-wilt virus, tobacco-ringspot virus, and Bergerac-ringspot virus.

**Filterability:** Passes membranes down to 40 millimicrons average pore diameter.

**Other properties:** Virus crystallizes from solutions of ammonium sulfate as isotropic, rhombic dodecahedra, which shrink and swell reversibly on drying and

rewetting; shrinkage reduces size to 80 per cent of the wet dimensions. In the presence of heparin, non-birefringent prisms, rather than dodecahedra, appear.  $S_{20}^{20} = 132 \times 10^{-14}$  cm. sec.<sup>-1</sup> dyne<sup>-1</sup>. Particle approximately spherical, 27.4 millimicrons in diameter by X-ray measurements (average diameter by filtration data, 14 to 20 millimicrons). Solutions do not show anisotropy of flow. Inactivated by drying. Molecular weight 8,800,000. Density 1.353. Molecular weight may be as high as 21,000,000 in solution, but the density is then lower, 1.286. Analysis: carbon 47 to 50 per cent, nitrogen 15.8 to 16.4 per cent, phosphorus 1.3 to 1.5 per cent, ash 1.7 to 5 per cent, hydrogen 7.2 to 8.2 per cent, sulfur 0.4 to 0.8 per cent, carbohydrate 5 to 6 per cent.

Biol., 22, 1935, 731-741; Jour. Roy. Hort. Soc., 60, 1935, 448-451; Smith and MacClement, Parasitol., 33, 1941, 320-330; Stanley, Jour. Biol. Chem., 155, 1940, 437-454.

#### Key to the species of the Tobacco-Etch Virus Group.

Viruses relatively susceptible to heat inactivation (inactivated at 52 to 58° C in 10 minutes)  
other, if

I.

of the group in tobacco.

II. Replaced by No. 6, not by No. 8, if in mixture with it in tobacco.

III. Replaced by No. 6 or 7 if in mixture with either in tobacco.

6 *Marmor erodens*.

7 *Marmor hyoscyami*.

8 *Marmor upslon*.

group; dominant member

*G. Marmor erodens* Holmes. (Holmes, Handb. Phytopath. Viruses, 1939, 40; *Foliopellis erodens* Valleau, Phytopath., 50, 1910, 825) From Latin *erodere*, to erode or gnaw away.

Common name: Tobacco-etch virus

Hosts: *SOLANACEAE*—*Capsicum frutescens* L., pepper; *Datura stramonium* L., Jimson weed; *Lycopersicon esculentum* Mill., tomato, *Nicotiana tabacum* L., tobacco, *Petunia* sp., petunia; *Physalis heterophylla* Nees

Geographical distribution: United States.

Induced disease: In tobacco, systemic mild-mottling chlorosis, with traces of necrotic etching; intranuclear crystalline inclusions and intracytoplasmic granular and amorphous inclusions that tend to crystallize, forming needle-shaped birefringent bodies, 2 to 10 microns in length.

Transmission: Experimentally, by *Myzus persicae* (Sulz.), *M. circumflexus* (Buckt.), *Aphis rhamni* Boyer, *A. fabae* (Scop.), and *Macrosiphum gei* (Koch) (*APHIDIDAE*), by inoculation of expressed juice.

Serological relationships: Precipitin reactions with homologous antisera, but no cross-reactions with tobacco-mosaic virus, tobacco-ringspot virus, potato-mottle virus, potato aucuba-mosaic virus, potato mild mosaic virus, hyoseyamus-mosaic virus, potato-veinbanding virus, or pea mosaic virus.

Immunological relationships: Protects tobacco against subsequent infection by potato veinbanding virus and hyoseyamus-mosaic virus. In mixed infections, it suppresses and replaces these two viruses.

Thermal inactivation: At 53 to 55° C in 10 minutes.

Filterability: Passes Pasteur Chamberland L<sub>2</sub>, not L<sub>3</sub>, filter candle.

Other properties: Sedimentation constant  $S_{20}^{70} = 170 \times 10^{-13}$  cm. sec.<sup>-1</sup> dyne<sup>-1</sup>. Concentrated preparations show anisotropy of flow, in heating elongated particle shape.

Literature: Rowden and Kassanis, Ann

Appl. Biol., 28, 1941, 107-118; Fernow, Cornell Agr. Exp. Sta. (Ithaca), Mem. 96, 1925; Holmes, Phytopath., 52, 1912, 1058-1067; Johnson, Kentucky Agr. Exp. Sta., Res. Bull. 306, 1930.

Strains: A distinctive severe-symptom strain, isolated from plants infected in nature and studied intensively, has been distinguished from the type, var. *vulgare* II. (*loc. cit.*, 40), by the varietal name:

6a *Marmor erodens* var. *sererum* II. (*loc. cit.*, 41) Differing from the type by a tendency to induce more pronounced necrotic etching and a greater stunting effect in infected tobacco.

7. *Marmor hyoseyamii* spec. nov. From New Latin *Hyoseyamus*, genus name of plant from which this virus was first isolated.

Common names: Hyoseyamus-mosaic virus, Hy. III virus, Hyoseyamus-III-disease virus.

Hosts: *SOLANACEAE*—*Hyoseyamus niger* L., henbane. Experimentally, also *Nicotiana tabacum* L., tobacco.

Insusceptible species: *CUCURBITACEAE*—*Cucumis sativus* L., cucumber.

Geographical distribution: England.

Induced disease: In henbane, chlorotic clearing of veins followed by yellow-mottling mosaic.

Transmission: By inoculation of expressed juice to dilutions of  $10^{-4}$ . By aphids, *Myzus persicae* (Sulz.), *M. circumflexus* (Buckt.), and *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch) (*APHIDIDAE*).

Serological relationships: Several isolates of this virus give mutual cross-precipitin reactions but no precipitation occurs when antiserum prepared with this virus is mixed with cucumber mosaic virus, tobacco-etch virus, or potato veinbanding virus.

Immunological relationships: No immunity with respect to this virus is induced in tobacco by previous infection with cucumber mosaic virus. Potato-veinbanding virus is unable to multiply in the presence of this virus and is replaced by it. Tobacco-etch virus pro-

fects against this virus and replaces it in mixed infections.

Thermal inactivation: At 58° C in 10 minutes.

Filterability: Passes Chamberland L<sub>1</sub>, but not L<sub>2</sub>, filter candles.

Other properties: Concentrated solutions show anisotropy of flow. Yield of virus, 1 to 3 mg per liter of juice expressed from diseased tobacco plants.

Literature: Bawden and Kassanis, *Ann. Appl. Biol.*, 28, 1941, 107-118; Hamilton, *ibid.*, 19, 1932, 550-567; Sheffield, *ibid.*, 25, 1938, 781-789, Watson and Roberts, *Proc. Roy. Soc. London, Ser. B*, 127, 1939, 543-576.

8. *Marmor upsilon comb. nov.* (*Marmor cucumeris* var. *upsilon* Holmes, *loc. cit.*, 33; *Murialba renataenta* Valteau, *Phytopath.*, 50, 1940, 821) From Greek name of the letter Y, sometimes used to denote this virus.

Common names. Potato-veinbanding virus, potato virus Y.

Hosts: *SOLANACEAE*—*Solanum tuberosum* L., potato, *Nicotiana tabacum* L., tobacco. Experimentally, also *Lycium barbarum* L.

Geographical distribution: England, France, United States, Brazil. Rare in Scotland and part of Ireland.

Induced disease. In some potato varieties, leaf drop and necrotic stem-streak; in others, no signs of disease; in still others, chlorotic mottling with or without necrosis. In combination with strains of the potato-mottle virus (*Marmor dubium*), this virus causes rugose mosaic, a common and destructive double-virus disease.

Transmission: By inoculation of expressed juice. By aphid, *Myzus persicae* (Sulz.); experimentally, also by *Aphis rhamni* Boyer (synonym for *Aphis abbreviata* Patch) (*APHIDIDAE*).

Serological relationships: Precipitation reactions with homologous antisera. No cross reactions with tobacco-mosaic virus, tobacco-etch virus, hyoscyamus-mosaic virus, potato-mottle virus, potato mild-mosaic virus, potato aucuba-mosaic virus, tobacco-ringspot virus, or common pea-mosaic virus. Reported cross reaction with cucumber-mosaic virus needs confirmation.

Immunological relationships: A mild strain protects against subsequent infection with the typical virus. This virus is suppressed and replaced by hyoscyamus-mosaic virus and by tobacco-etch virus in mixed infections.

Thermal inactivation: At 52° C in 10 minutes.

Filterability: Passes with difficulty through Gradocol membrane of 42 millimicron average pore diameter.

Other properties: Inactivated by drying.

Literature: Dennis, *Nature*, 142, 1938, 154; Johnson, *Phytopath.*, 25, 1935, 650-652; Jones and Vincent, *Jour. Agr. Res.*, 55, 1937, 69-79; Kassanis, *Ann. Appl. Biol.*, 29, 1942, 95; Koch, *Phytopath.*, 23, 1933, 319-342; Kramer and Silberschmidt, *Arquivos Inst. Biol. São Paulo, Brazil*, 11, 1940, 165-188; Salaman, *Nature*, 159, 1937, 924; Smith, *Proc. Roy. Soc., Ser. B*, 109, 1931, 251-267; Smith and Dennis, *Ann. Appl. Biol.*, 27, 1940, 65-70.

#### Key to the species of the Cucumber-Mosaic Virus Group.

Viruses relatively susceptible to heat inactivation, requiring less than 10 minutes at 85 to 90° C for complete inactivation. Not replacing potato-veinbanding virus in mixed infections.

I. Infecting both dicotyledonous and monocotyledonous plants.

9. *Marmor cucumeris*

II. Infecting dicotyledonous, but not monocotyledonous, plants.

10. *Marmor solani*.

11. *Marmor aucuba*.

12. *Marmor umbelliferarum*.

13. *Marmor cruciferarum*.
14. *Marmor brassicae*
15. *Marmor betae*.
16. *Marmor lactucae*.
17. *Marmor dahliae*.
18. *Marmor phaseoli*.
19. *Marmor leguminosarum*.
20. *Marmor pisi*
21. *Marmor medicaginis*.
- not dicotyledonous, plants.
22. *Marmor tulipae*.
23. *Marmor mife*.
24. *Marmor iridis*.
25. *Marmor sacchari*.
26. *Marmor cepae*
27. *Marmor scillarum*.

### III. Infecting monocotyledonous, but

9. *Marmor cucumeris* Holmes (Holmes, Handb. Phytopath. Viruses, 1939, 31; *Murialba cucumeris* Valteau, Phytopath., 50, 1910, 823.) From Latin *cucumis*, cucumber.

Common name. Cucumber-mosaic virus

Hosts. Very wide range of hosts among dicotyledonous and monocotyledonous plants, cucumber, celery, spinach, tobacco, and pepper are sometimes seriously affected. Overwintering hosts are. **SOLANACEAE**—*Physalis subglabrata* MacKenzie and Bush, *P. heterophylla* Nees **ASCLEPIADACEAE**—*Asclepias syriaca* L. **PHYTOLACCACEAE**—*Physalis decandra* L. **LABIATAE**—*Nepeta cataria* L. Probably there are also other susceptible perennials.

Geographical distribution. Probably all most world wide

Induced disease. In cucumber, *Cucumis sativus* L., yellowish green systemic mottling. Leaves small, distorted, curled, plants dwarfed, internodes shortened. Few fruits set. Fruits mottled, misshapen, giving the disease the name "white pickle." In black currant, *Vigna sinensis* (L.) Endl., small reddish necrotic local lesions only. No intracellular bodies are found in plants infected with cucumber mosaic virus.

Transmission. By inoculation of expressed juice. By aphids, *Myzus persicae* (Sulz.), *M. pseudosclani* Theob., *M.*

*circumflexus* (Buckt.), *Macrosiphum solanifolius* Ashm., and *Aphis gossypii* Glov. (**APHIDIDAE**). Through seeds of diseased plants in *Echinocystis lobata* (Michx.) Torr and Gray, wild cucumber, in *Cucumis melo* L., muskmelon, and in *Cucurbita pepo* L., vegetable marrow. By several species of dodder, *Cuscuta californica* Choisy, *C. campestris* Yunker, and *C. subinclusa* Dur and Hilg (**CONVOLVULACEAE**).

Immunological relationships. Infection with the type and other elaborative-motting strains protects zinnia against subsequent infection by an indicator strain of this virus (var. *judicis*).

Thermal inactivation. At 70 to 80° C in 10 minutes.

Filterability. Passes Berkefeld W and N filters and collodion membranes of 45 millimicron average pore diameter.

Other properties. Inactivated by drying or 3 to 4 days' storage in juice at room temperature.

Literature. Ainsworth, Ann Appl. Biol., 25, 1938, 867-869; Chamberlain, New Zealand Jour. Science and Technology, 21, 1939, 73 A-90 A; Celino, Philippine Agr., 23, 1910, 373-414; Doobittle, Phytopath., 6, 1916, 143-147; U. S. Dept. Agr., Bull. 879, 1920; Doobittle and Walker, Jour. Agr. Res., 31, 1923, 1-58; Gilbert, Phytopath., 6, 1916, 143-144; Huggan, Jour. Agr. Res., 47, 1923, 689-701; Jagger, Phytopath., 6, 1916, 148-151;

8, 1918, 32-33; Kendrick, *Phytopath.*, 24, 1934, 820-823; Mahoney, *Proc. Am. Soc. Hort. Sci.*, 322, 1935, 477-480; Price, *Phytopath.*, 25, 1935, 776-789; 29, 1939, 903-905; *Am. Jour. Bot.*, 27, 1940, 530-541; Storey, *Ann. Appl. Biol.*, 26, 1939, 298-308.

Strains: Various host plants seem to have induced specialization of cucumber-mosaic virus in strains particularly adapted to existence in their tissues. Several of these and certain laboratory-derived strains useful in technical procedures have been distinguished from the type, var. *vulgare* H. (*loc. cit.*, 31), by varietal names, as follows:

9a. *Marmor cucumeris* var. *commelinae* H. (*loc. cit.*, 35). From New Latin *Commelina*, generic name of weed serving as a natural reservoir of this strain. Common name: Southern celery-mosaic strain of cucumber-mosaic virus. Differing from the type in severity of disease induced in celery and some other plants. Transmitted by *Aphis gossypii* Glov., *A. maidis* Fitch, and *Pentalonia nigronervosa* Coq. (*APHIDIDAE*). (Price, *Phytopath.*, 25, 1935, 947-954; Wellman, *ibid.*, 24, 1934, 695-725, 1032-1037, 25, 1935, 289-308, 377-404.)

9b. *Marmor cucumeris* var. *phaseoli* H. (*loc. cit.*, 36). From New Latin *Phaseolus*, generic designation of lima bean. Common name: Lima-bean strain of cucumber-mosaic virus. Differing from type of species in ability to cause a chlorotic mottling disease in lima bean in nature. (Harter, *Phytopath.*, 26, 1936, 94, *Jour. Agr. Res.*, 56, 1938, 895-906, McClintock, *Phytopath.*, 7, 1917, 60.)

9c. *Marmor cucumeris* var. *lilii* H. (*loc. cit.*, 37). From Latin *lilium*, lily. Common name: Lily-mosaic strain of cucumber-mosaic virus. Differing from the type variety by ability to persist in nature in lilies, producing masked infection or chlorotic mottling unless in mixture with lily-symptomless virus (*Adelonus lili*), when a more severe disease involv-

ing necrosis is induced. (Brierley, *Phytopath.*, 29, 1939, 3; 30, 1940, 230-237, Brierley and Doolittle, *ibid.*, 30, 1940, 171-174; Ogilvie and Guterman, *ibid.*, 19, 1929, 311-315; Price, *ibid.*, 27, 1937, 561-569.)

9d. *Marmor cucumeris* var. *judicis* H. (*loc. cit.*, 38). From Latin *judex*, judge. Common name: Indicator strain of cucumber-mosaic virus. Differing from the type variety in inducing the formation of necrotic local lesions in zinnia (*Zinnia elegans* Jacq., *COMPOSITAE*). Previous infection of zinnia by other strains of cucumber-mosaic virus inhibits the formation of these necrotic local lesions, identifying the strains as related to each other and to the indicator strain. (Price, *Phytopath.*, 24, 1934, 743-761; 25, 1935, 776-789.)

9e. *Marmor cucumeris* var. *vignae* H. (*loc. cit.*, 39). From New Latin *Vigna*, generic name of cowpea. Common name: Cowpea-mottling strain of cucumber-mosaic virus. Differing from the type variety in producing systemic chlorotic mottling, rather than reddish-brown necrotic local lesions, in black cowpea. Not known in nature but derived experimentally from a mild-mottling strain of cucumber-mosaic virus during serial passage in cowpea. (Price, *Phytopath.*, 24, 1934, 743-761; 25, 1935, 776-789.)

10. *Marmor solani* H. (*loc. cit.*, 47). From New Latin *Solanum*, generic name of potato.

Common names: Potato mild-mosaic virus, potato virus A.

Hosts: *SOLANACEAE*—*Solanum tuberosum* L., potato. Experimentally, also *Nicotiana tabacum* L., tobacco; *Solanum nigrum* L. var. *nodiflorum*; and *Datura stramonium* L., Jimson weed.

Geographical distribution: United States, England, Holland.

Induced disease: In potato, very mild chlorotic mottling or masked symptoms in some varieties (as Irish Chiefstain), systemic necrosis in others (for example,

Optimum temperature 37°C.

Subcutaneous and intravenous inoculations into rabbits cause death in 36 to 48 hours.

Source: Isolated from nasal secretions in arena.

17. *Pseudomonas chlorina* (Frankland and Frankland) Levine and Soppeland (*Bacillus chlorinus* G. and P. Frankland, Philos. Trans. Roy. Soc. London, 178, 1887, 274; *Bacterium chlorinum* Migula, Syst. d. Bakt., 2, 1900, 471, Levine and Soppeland, Bul. No. 77, Iowa State Agricultural College, 1926) From Greek, *chloros*, greenish yellow

Rods: 0.5 by 1.5 micron, occurring singly and in short chains. Non-motile. Gram-negative.

Gelatin stab: Crateriform liquefaction with green fluorescence. Lemon yellow sediment.

Agar colonies: Circular, raised, smooth, amorphous, entire, becoming greenish yellow.

Agar slant: Slightly raised, glistening, the medium becoming light greenish yellow.

Broth: Moderate turbidity. Dirty yellow sediment. No pellicle.

Litmus milk: Peptonized. Litmus reduced.

Potato: Scant, olive green growth.

Indole formed.

Nitrites produced from nitrates.

Starch hydrolyzed.

Blood serum liquefied in 5 days.

Acid from glucose.

Aerobic, facultative.

Optimum temperature 22°C.

Source: Air.

18. *Pseudomonas oleovorans* Lee and Chandler, (Jour. Bact., 41, 1941, 378) From M. L. oil destroying.

Short rods, 0.5 by 0.8 to 1.5 microns, occurring singly and in pairs. Motile. Gram-negative.

Gelatin stab: No liquefaction after 6 weeks.

Gelatin colonies: Up to 1 mm in diameter, fluorescent, similar to agar colonies.

Surface agar colonies: After 24 hours 1 to 2 mm. in diameter, smooth, convex, shiny, opaque, creamy, fluorescent by transmitted light. Edge entire in young colonies.

Deep agar colonies: 0.5 by 1.0 to 1.5 mm, lens-shaped, buff-colored, not fluorescent.

Agar slant: Growth raised, smooth, fluorescent, edge erose.

Broth: After 24 hours moderate turbidity with slight yellowish viscid sediment. No pellicle or ring.

Litmus milk: No change.

Indole not formed.

Potato: Good growth.

Nitrites are produced from nitrates.

Starch is hydrolyzed.

No acid from glucose, lactose, sucrose, galactose, xylose, mannitol, salicin and glycerol.

Equally good growth at 25° and 37°C.

Aerobic.

Distinctive character: The fluorescent quality of the colonies is not imparted to any of the artificial media used.

Source: Isolated from cutting compound (oil-water emulsion) circulating in a machine shop. The oil in this compound may be utilized as a sole source of energy.

Habitat: Probably oil soaked soils. Abundant in cutting compounds.

19. *Pseudomonas incognita* Chester (*Bacillus fluorescens incognitus* Wright, Memoirs Nat. Acad. Sci., 7, 1895, 436, Chester, Determinative Bacteriology, 1901, 323) From Latin, *in*, not, *copito*, to think, M. L. unknown.

Short rods, with rounded ends, occurring singly, in pairs and in chains. Motile, possessing a polar flagellum. Gram-negative.

Gelatin colonies: Thin, transparent, slightly granular, becoming greenish. Margin undulate. The medium assumes a blue green fluorescence.

1937, 903-912; Dykstra, *Phytopath.*, 29, 1939, 917-933.)

12. *Marmor umbelliferarum* H. (loc. cit., 67). From New Latin *Umbelliferae*, family name of plants among which celery is classified.

Common name: Celery-mosaic virus, western celery-mosaic virus.

Hosts: *UMBELLIFERAE*—*Apium graveolens* L., celery and celeriac; *Daucus carota* L., carrot. Experimentally, also *Anethum graveolens* L., dill; *Anthriscus cerifolium* (L.) Hoffm., salad chervil; *Carum carvi* L., caraway; *Coriandrum sativum* L., coriander; *Petroselinum hortense* Hoffm., parsley.

Insusceptible species: *Cucumis sativus* L., cucumber, and all other tested species not of the family *Umbelliferae*.

Geographical distribution: United States (California).

Induced disease In celery, at first, clearing of veins in young leaves; later, foliage yellowed, plant stunted, young petioles shortened older petioles horizontal, giving plant a flat appearance. Foliage mottled green and yellow; leaflets narrow, twisted or cupped; older leaves with some necrosis; petioles with white streaks or spots. In celeriac, clearing of veins, followed by systemic chlorotic mottling. In carrot, chlorotic spotting of young leaves, followed by systemic chlorotic mottling.

Transmission: By inoculation of expressed juice, in dilutions to 1:4000. No specific insect vector is known, but 11 species of aphids capable of breeding on celery transmit the virus, though they do not long retain the power of transmission after leaving diseased plants. These vectors are *Aphis apigraveolens* Essig, *A. apii* Theob., *A. ferruginea-striata* Essig, *A. gossypii* Glov., *A. middletoni* Thomas, *A. rumicis* Linn., *Carottella capreae* (Fabr.), *Myzus circumflexus* (Buckt.), *M. convolvuli* (Kalt), *M. persicae* (Sulz.), *Rhopalosiphum melliferum* (Hottes) (*APHIDIDAE*). Some

aphids not able to breed on celery also transmit this virus.

Thermal inactivation: At 55 to 60° C in 10 minutes.

Filterability: Passes all grades of Chamberland filters.

Other properties: Virus active after storage at -18° C for 18 months.

Literature: Severin and Freitag, *Hilgardia*, 11, 1938, 493-553.

13. *Marmor cruciferarum* H. (loc. cit., 69). From New Latin *Cruciferae*, family name of plants among which cauliflower is classified.

Common name: Cauliflower-mosaic virus.

Hosts: *CRUCIFERAE*—*Brassica oleracea* L., cauliflower, kale, Brussels sprouts, cabbage, and broccoli; *B. campestris* L., wild yellow mustard; *Malthiola incana* R. Br., annual stock. Experimentally, also *Brassica adpressa* Boiss; *B. alba* Rabenh., white mustard, *B. arvensis* (L.) Ktze., charlock; *B. juncea* Coss., leaf mustard (one strain not susceptible); *B. napus* L., rape; *B. pe-tsai* Bailey, pe-tsai; *B. nigra* Koch, black mustard; *B. rapa* L., turnip; *Capsella bursa-pastoris* Medic., shepherd's purse; *Iberis amara* L., rocket candytuft; *Leptidium sativum* L., garden cress, *Lunaria annua* L., honesty; *Raphanus raphanistrum* L., white chaulock; *R. sativus* L., radish.

Insusceptible species: *CHENOPODIACEAE*—*Spinacia oleracea* L. *COMPOSITAE*—*Lactuca sativa* L. *CRUCIFERAE*—*Alyssum saxatile* L.; *A. maritimum* Lam.; *Arabis alba* Stev.; *Athysanus pusillus* Greene; *Brassica juncea* Coss. (Japanese strain; another strain susceptible); *Cheiranthus cheiri* L.; *Erysimum perofskianum* Fisch. and Mey.; *Hesperis matronalis* L.; *Malcomia maritima* R. Br.; *Roripa nasturtium* Rusby; *Stanleya pinnata* (Pursh.) Britt.; *Thysanocarpus radians* Benth. *LEGUMINOSAE*—*Vicia faba* L. *SOLANACEAE*—*Capsicum frutescens* L.; *Lycoper-*

British Queen). Immunity to aphid infection with this virus is found in the varieties Katahdin and Earlsine. A combination disease, characterized by pronounced yellow-mosaic patterns, is caused by this virus in the variety Irish Chieftain if the potato-veinbanding virus (*Marmor epsilon*) is also present. In tobacco, experimentally, faint veinbanding mosaic.

Transmission: To potato, by rubbing methods of inoculation of expressed juice, using carborundum powder; to tobacco, by rubbing without carborundum. By aphids, *Aphis abbreviata* Patch and *Myzus persicae* (Sulz.) (*APHIDIDAE*).

Serological relationships: No cross-precipitin reactions with potato aucubamosaic virus, potato-veinbanding virus, tobacco-mosaic virus, tobacco-etch virus, tobacco-ringspot virus, or pea mosaic virus.

Immunological relationships. A feeble strain of this virus has been found to protect fully against the typical strain in the Netherlands.

Thermal inactivation: At 50° C in 10 minutes.

Literature: Bawden, Ann. Appl. Biol., 23, 1936, 457-497; Chester, Phytopath., 25, 1935, 686-701; Dykstra, Phytopath., 29, 1939, 40-67; Hansen, Tidsskr. Planteavl., 42, 1937, 631-651; Murphy and Loughnane, Sci. Proc. Roy. Dublin Soc., 21, 1936, 419-430; Murphy and McKay, *ibid.*, 30, 1932, 227-237; Oortwijn Botjes, Tijdsch. Plantenziekten, 45, 1933, 25-29; Schultz et al., Phytopath., 27, 1937, 190-197; 30, 1940, 911-951.

II *Marmor aucuba* II (*loc. cit.*, 49)  
From New Latin *Aucuba*, a genus of plants having mottled foliage.

Common name: Potato aucuba mosaic virus.

Hosts: *SOLANACEAE*—*Solanum tuberosum* L., potato. Experimentally, also *Atropa belladonna* L. (symptomless), *Capsicum frutescens* L., pepper, *Datura stramonium* L., Jimson weed (symptomless), *Hyoscyamus niger* L., henbane

(symptomless); *Lycopersicon esculentum* Mill., tomato; *Petunia hybrida* Vilm., *petunia* (symptomless); *Nicotiana glauca* L., tobacco (symptomless); *Solanum dulcamara* L., bittersweet; *S. nigrum* L. var. *nodiflorum*.

Geographical distribution: United States, Great Britain, Europe.

Induced disease: In potato, yellow spots on lower leaves of some varieties; in the variety Irish Chieftain, brilliant yellow mottle over whole plant, perhaps because of simultaneous presence of potato mild-mosaic virus in this variety. Necrosis of the cortex and of the pith in tubers in many varieties.

Transmission: By inoculation of expressed juice. Probably by aphid, *Myzus persicae* (Sulz.) (*APHIDIDAE*).

Serological relationships: No precipitin cross-reactions with potato mild-mosaic virus, potato-veinbanding virus, tobacco-mosaic virus, tobacco-etch virus, tobacco-ringspot virus, or pea-mosaic virus. Precipitin cross-reactions with the Canada-streak strain of potato aucubamosaic virus.

Thermal inactivation: At 65 to 68° C in 10 minutes.

Filterability: Passes Pasteur-Chamberland  $I_4$  filter, but not  $I_2$  or  $L_4$ .

Literature: Chester, Phytopath., 25, 1935, 686-701; 27, 1937, 903-912; Clinch, Sci. Proc. Roy. Dublin Soc., 22, 1911, 435-445; Clinch et al., *ibid.*, 21, 1936, 431-448; Dykstra, Phytopath., 29, 1939, 917-933.

Strains: One strain differing from the type has been given a varietal name:

IIa *Marmor aucuba* var. *canadense* Black and Price (Phytopath., 30, 1940, 111) From common name of strain.

Common name: Canada streak strain of potato aucuba mosaic virus. Differing from the type variety by tendency to produce necrosis in stems, veins, petioles, and leaves and also, about 2 months after harvest, in pith of tuber, especially at stem end. (Chester, Phytopath., 27,

under identical circumstances. More work is needed to show existing alliances.

Literature: Chamberlain, New Zealand Jour. Agr., 58, 1936, 321-330; New Zealand Jour. Science and Technology, 21, 1939, 212A-223A; Clayton, Jour. Agr. Res., 40, 1930, 263-270; Gardner and Kendrick, *ibid.*, 22, 1921, 123-124; Hoggan and Johnson, Phytopath., 25, 1935, 640-644; Larson and Walker, Jour. Agr. Res., 57, 1938, 589-602; 58, 1939, 63-77; Tompkins et al., *ibid.*, 57, 1938, 929-943.

15. Marmor betae H. (*loc. cit.*, 72). From Latin *beta*, beet.

Common name: Sugar-beet mosaic virus.

Hosts: *CHENOPODIACEAE*—*Beta vulgaris* L., beet; *Spinacia oleracea* L., spinach.

Geographical distribution: France, Denmark, Germany, Sweden, United States, England.

Induced disease: In beet, discrete yellowish secondary lesions or clearing of veins on young leaves, followed by chlorotic mottling of newly formed leaves. Darkening of vascular tissue. Leaves bend back near tips, which sometimes die. Intracellular bodies formed. In spinach, 6 to 21 days after infection, chlorotic flecks on young leaves. Plant stunted, outer leaves killed, dying from their tips back. Center of plant survives for a time, but finally dies.

Transmission: By inoculation of expressed juice, in dilutions to  $10^{-2}$ . By aphids, *Myzus persicae* (Sulz.), *Aphis rumicis* Linn., and perhaps *Macrosiphum solanifolii* Ashm. (= *M. gae* Koch) (*APHIDIDAE*). No seed transmission.

Thermal inactivation: At 55 to 60° C in 10 minutes.

Other properties: Inactivated by standing in expressed juice for 24 to 48 hours at about 70° F.

Literature: Böning, Försch. Geb. Pflanzenkr. u. Immun. Pflanzenreich, 3, 1927 81-128; Cent. f. Bakt., II Abt., 71, 1927, 490-497; Gratia and Manil, Compt. rend. Soc. Biol., Paris, 118, 1935, 379-381; Hoggan, Phytopath., 23, 1933, 446-474; Jones, Washington Agr. Exp. Sta. Bull. 250, 1931; Lind, Tidsskr. Planteavl, 22, 1915, 444-457; Robbins, Phytopath., 11, 1921, 349-363; Schmidt, Ber. Deutsch. Bot. Ges., 45, 1927, 598-601.

16. Marmor lactucae H. (*loc. cit.*, 84). From Latin *lactuca*, lettuce.

Common name: Lettuce-mosaic virus.

Hosts: *COMPOSITAE*—*Lactuca sativa* L., lettuce; *Senecio vulgaris* L., groundsel. Experimentally, also *COMPOSITAE*—*Sonchus asper* Hoffm., prickly sow-thistle. *LEGUMINOSAE*—*Lathyrus odoratus* L., sweet pea; *Pisum sativum* L., pea.

Insusceptible species: *COMPOSITAE*—*Sonchus oleraceus* L., *S. arvensis* L., *Taraxacum officinale* Web., *Carduus arvensis* Curt. *CRUCIFERAE*—*Bras-*

*stramonium* L.

Geographical distribution: United States, England, Germany, Bermuda.

Induced disease: In lettuce varieties, clearing of veins followed by systemic chlorotic mottling, dwarfing and defective hearting, sometimes by scorching of leaf edges, vein necrosis or necrotic flecking between veins.

Transmission: By inoculation of expressed juice, in dilutions to 1:100 if mixed with a little 0.5 per cent sodium sulphite solution and a trace of powdered carborundum. By aphids, *Myzus persicae* (Sulz.) and *Macrosiphum gae* Koch (*APHIDIDAE*). Through seeds from diseased plants. It is believed that seed-borne virus is the most important source of primary inoculum in the spring.

Thermal inactivation: At 55 to 60° C in 10 minutes.

*sicon esculentum* Mill.; *L. pimpinellifolium* Mill.; *Nicotiana glutinosa* L.; *N. langsdorffii* Weinm.; *N. tabacum* L. var. Turkish and White Burley. **TROPAEOLACEAE**—*Tropaeolum majus* L. **UMBELLIFERAE**—*Apium graveolens* L.

Geographical distribution: United States, England.

Induced disease: In cauliflower, clearing of veins, followed by mild chlorotic mottling, veins usually banded with dark green, necrotic flecks later in chlorotic areas. Midrib curved, leaves distorted. Plant stunted; terminal head or curd dwarfed. Solanaceous plants appear to be immune, a point of distinction between this virus and turnip-mosaic virus, *Marmor brassicae*.

Transmission: By inoculation of expressed juice, using carborundum powder. By many aphid species, *Brevicoryne brassicae* (Linn.), cabbage aphid; *Rhopalosiphum pseudobrassicae* Davis, false cabbage aphid, *Myzus persicae* (Sulz.), peach aphid; *Aphis graveolens* Essig, celery leaf aphid; *A. apigraveolens* Essig, celery aphid, *A. middletonii* Thomas, erigeron root aphid; *A. gossypii* Glov., cotton aphid, *Corariella capreae* (Fabr.), yellow willow aphid, *Myzus circumflexus* (Buckt.), lily aphid; *Rhopalosiphum meliferum* (Hottes), honeysuckle aphid (**APHIDIDAE**). No seed transmission.

Thermal inactivation: At 75° C in 10 minutes.

Literature: Caldwell and Prentice, Ann Appl Biol., 29, 1942, 366-373, 374-379, Rawlins and Tompkins, Phytopath., 34, 1931, 1147 (Abstr.); Tompkins, Jour Agr Res., 33, 1937, 33-46.

14. *Marmor brassicae* H. (H., loc. cit., 70, *Marmor Matthiolae* H., loc. cit., 71) From New Latin, *Brassica*, generic name of turnip.

Common name: Turnip mosaic virus. Hosts: **CRUCIFERAE**—*Brassica rapa* L., turnip, *B. napobrassica* Mill., swede or rutabaga; *B. napus* L., rape; *B.*

*nigra* (L.) Koch, black mustard; *B. oleracea* L., cabbage; *Armoracia rusticana* Gaertn., horse-radish; *Cheiranthus cheiri* L., wallflower; *Matthiola incana* R. Br., stock; *Sinapis alba* L., white mustard. Experimentally, also **CRUCIFERAE**—*Berteroa incana* (L.) DC; *Brassica alba* Rabenh., white mustard; *B. arvensis* (L.) Ktze.; *B. chinensis* L., Chinese cabbage; *B. juncea* (L.) Coss.; *Capsella bursa-pastoris* (L.) Medic.; *Cardamine heterophylla* (Forst. f.) O. E. Schultz; *Cheiranthus allionii* Hort; *Coronopus didymus* Smith; *Hesperis matronalis* L.; *Lepidium rudemale* L.; *L. sativum* L., *L. virginicum* L.; *Nasturtium officinale* R. Br.; *Neslia paniculata* (L.) Desv.; *Radiola palustris* (L.) Moench; *Raphanus sativus* L.; *Sisymbrium altissimum* L.; *S. officinale* (L.) Scop; *Thlaspi arvense* L. **CHENOPODIACEAE**—*Beta vulgaris* L.; *Spinacia oleracea* L., spinach. **COMPOSITAE**—*Calendula officinalis* L. *Zinnia elegans* Jacq. **RANUNCULACEAE**—*Delphinium ajacis* L. **SOLANACEAE**—*Lycopersicon pimpinellifolium* Mill., *Nicotiana bigelovii* S. Wats.; *N. glutinosa* L., *N. langsdorffii* Weinm., *N. repanda* Willd., *N. rustica* L.; *N. sylvestris* Speg. and Comes; *N. tabacum* L., tobacco, *Petunia hybrida* Vilm.

Geographical distribution: United States, England, New Zealand.

Induced disease: In turnip, systemic chlorotic mottling; plants stunted, leaves distorted. In tobacco, experimentally, characteristic necrotic primary lesions only.

Transmission: By inoculation of expressed juice. By cabbage aphid, *Brevicoryne brassicae* (Linn.), and by the peach aphid, *Myzus persicae* (Sulz.) (**APHIDIDAE**).

Thermal inactivation: At 54° C in 10 minutes.

Strains: A considerable number of strains of this virus appear to occur in nature, but those that have been studied often have been considered as distinct viruses and not compared with each other.

ally, also *Cicer arietinum* L.; *Desmodium canadense* (L.) DC.; *Lathyrus sativus* L., grass pea; *Lupinus albus* L., white lupine; *L. angustifolius*, blue lupine; *L. densiflorus* Benth.; *L. hartwegii* Lindl.; *L. nanus* Dougl.; *Medicago arabica* Huds., spotted bur clover; *M. hispida* Gaertn., oothed bur clover; *Melilotus alba* Desr., white sweet clover; *M. indica* All., annual yellow sweet clover; *M. officinalis* (L.) Lam., yellow sweet clover; *Phaseolus acutifolius* Gray, tepary bean; *P. vulgaris* L., bean; *Trifolium agrarium* L.; *T. carolinianum* Michx.; *T. dubium* Sibth.; *T. glomeratum* L., cluster clover; *T. hybridum* L., alsike clover; *T. incarnatum* L., crimson clover; *T. procumbens* L.; *T. reflexum* L.; *T. suaveolens*, Persian clover; *Vicia sativa* L., common vetch.

**Insusceptible species:** All tested species in families other than the *Leguminosae*.

**Geographical distribution:** United States, British Isles, Europe, New Zealand.

**Induced disease:** In pea, clearing of veins in young leaves, followed by chlorosis of newly formed leaves, stunting of plant, and systemic chlorotic mottling. In sweet pea, systemic chlorosis and chlorotic mottling, flower colors broken. In lupine, necrotic streak on one side of stem, stunting of plant and bending of growing point to injured side. Plant soon wilts and dies. In *Vicia faba*, mottled leaves contain characteristic isometric crystals in host-cell nuclei (especially within nucleoli) as well as in cell cytoplasm.

**Transmission** By inoculation of expressed juice, with ease. By aphids, *Macrosiphum pisum* Kalt., *M. solanifolii* Ashm. (= *M. gae* Koch), and *Aphis rumicis* Linn. (*APHIDIDAE*). Not transmitted through seed.

**Serological relationships:** Specific precipitin reactions differentiate this virus from tobacco-mosaic virus, tobacco-etch virus, potato-mottle virus, potato mild-mosaic virus, potato aucuba-mosaic virus, and tobacco-ringspot virus.

**Thermal inactivation:** At 60° C in 10 minutes.

**Literature:** Chester, *Phytopath.*, 25, 1935, 686-701; Doolittle and Jones, *ibid.*, 15, 1925, 763-772; Johnson and Jones, *Jour. Agr. Res.*, 64, 1937, 629-633; McWhorter, *Phytopath.*, 31, 1941, 760-761; Murphy and Pierce, *ibid.*, 27, 1937, 710-721; Osborn, *ibid.*, 27, 1937, 589-603; Pierce, *Jour. Agr. Res.*, 61, 1935, 1017-1033; Spierenburg, *Tijdschr. Plantenz.*, 42, 1936, 71-76; Zaunmeyer and Wade, *Jour. Agr. Res.*, 63, 1936, 161-185.

20. Marmor pisi H. (*loc. cit.*, 90). From Latin *pisum*, pea.

**Common name:** Pea enation-mosaic virus.

**Hosts:** *LEGUMINOSAE*—*Pisum sativum* L., pea; *Vicia faba* L., broad bean. Experimentally, also *Lathyrus odoratus* L., sweet pea; *Soja max* (L.) Piper, soy bean; *Trifolium incarnatum* L., crimson clover.

**Insusceptible species:** *LEGUMINOSAE*—*Arachis hypogaea* L., peanut, *Medicago sativa* L., alfalfa; *Melilotus alba* Desr., white sweet clover; *M. officinalis* (L.) Lam., yellow sweet clover; *Phaseolus aureus* Roxb., mung bean; *P. vulgaris* L., bean; *Trifolium hybridum* L., alsike clover; *T. pratense* L., red clover; *T. repens* L., white Dutch clover. *SOLANACEAE*—*Lycopersicon esculentum* Mill., tomato; *Solanum tuberosum* L., potato.

**Geographical distribution:** United States, perhaps Germany.

**Induced disease:** In peas, systemic chlorotic mottling; in some varieties, as Alderman, occasional necrotic spots and numerous enations on lower surfaces of leaves. Pods distorted. In broad bean, systemic chlorotic spotting and striping of leaves. In sweet pea and soy bean, experimentally, systemic chlorotic mottling.

**Transmission:** By inoculation of expressed juice, using carborundum; more readily from aphid-inoculated plants than from mechanically-inoculated plants.

Filterability: Fails to pass L<sub>1</sub> Pasteur-Chamberland filter.

Literature: Ainsworth and Ogilvie, Ann Appl Biol., 26, 1939, 279-297; Jagger, Jour. Agr. Res., 20, 1921, 737-740; Newhall, Phytopath., 13, 1923, 104-106.

17. Marmor dahliae H. (loc. cit., 85). From New Latin *Dahlia*, generic name of host plant.

Common name: Dahlia-mosaic virus.

Hosts: COMPOSITAE—*Dahlia pinata* Cav., *dahlia*. Experimentally, also *D. imperialis* Roetzl.; *D. mazonsi* Safford.

Geographical distribution: United States, Holland, Germany, England

Induced disease: In intolerant varieties of dahlia, chlorotic mottling of foliage, leaf distortion, dwarfing of all stems and of roots, occasionally necrotic streaking of midveins. In tolerant varieties, inconspicuous chlorotic mottling or masked symptoms.

Transmission: By aphid, *Myzus persicae* (Sulz.) (APHIDIDAE). By grafting. Not by inoculation of expressed juice. Not through soil. Not through seeds from diseased plants.

Literature: Brietley, Am. Dahlia Soc. Bull., Ser. 9, No. 65, 1933; Contrib. Boyce Thompson Inst., 5, 1933, 235-288; Goldstein, Bull. Torrey Bot. Club, 54, 1927, 285-291.

18. Marmor phaseoli H. (loc. cit., 87). From New Latin *Phaseolus*, generic name of bean.

Common name: Bean mosaic virus.

Hosts: LEGUMINOSAE—*Phaseolus vulgaris* L., bean. Experimentally, also *Phaseolus acutifolius* Gray var. *latifolius* Freeman, *P. aureus* Roxb., *P. calcaratus* Roxb., *P. lunatus* L., *Leopedeza striata* (Thunb.) Hook. and Arn., *Vicia faba* L., *V. sativa* L., spring vetch.

Insusceptible species: LEGUMINOSAE—*Pisum sativum* L., garden pea; *Lathyrus odoratus* L., sweet pea.

Geographical distribution: World wide, wherever beans are grown.

Induced disease: In bean, first leaves

to be affected are crinkled, stiff, chlorotic; later leaves show chlorotic mottling; leaf margins often rolled down. Optimum temperature for expression of disease, 20 to 28° C, partial masking at 23 to 32° C, complete masking at 12 to 18° C.

Transmission: By inoculation of expressed juice in dilutions to 1:1000, using carborundum or other abrasive powder. By aphids, *Aphis rumicis* Linn., *Macrosiphum* (= *Illinoia*) *solanifolii* Ashm., *M. pisi* Kalt., *Aphis gossypii* Glov., *A. medicaginis* Koch, *A. spiraccola*, *Brevicoryne brassicae* (Linn.), *Hyalopterus atriplicis* Linn., *Macrosiphum ambrosiae* Thos., *Rhopalosiphum pseudobrassicae* Davis, and *Myzus persicae* (Sulz.) (APHIDIDAE). In beans, there is seed transmission to 30 to 50 per cent of plants grown from infected parents; pollen from infected plants is said to transmit virus.

Thermal inactivation: At 56 to 58° C in 10 minutes.

Literature: Fajardo, Phytopath., 20, 1930, 469-491, 883-888; Murphy, *ibid.*, 30, 1940, 779-781; Murphy and Pierce, *ibid.*, 28, 1938, 270-273; Parker, Jour. Agr. Res., 62, 1936, 895-915; Pierce, Phytopath., 24, 1934, 87-115, Jour. Agr. Res., 49, 1934, 183-188; 51, 1935, 1017-1039; Reddick, II Congr. Intern. Path. Comp., 1931, 363-366; Reddick and Stewart, Phytopath., 8, 1918, 530-531; Richards and Burkholder, Phytopath., 33, 1943, 1215-1216; Wade and Andrus, Jour. Agr. Res., 63, 1941, 389-393; Wade and Zaunmeyer, U. S. Dept. Agr., Circ. 500, 1934; Walker and Jolyette, Phytopath., 33, 1943, 778-788; Zaunmeyer and Kearns, *ibid.*, 26, 1936, 614-621; Zaunmeyer and Wade, Jour. Agr. Res., 61, 1935, 715-749.

19. Marmor leguminosarum H. (loc. cit., 80). From New Latin *Leguminosae*, family name of pea.

Common name: Pea mosaic virus.

Hosts: LEGUMINOSAE—*Lathyrus odoratus* L., sweet pea; *Pisum sativum* L., pea; *Trifolium pratense* L., red clover; *Vicia faba* L., broad bean. Experiment.

446). From New Latin *Solanum*, generic name of potato.

Common name. Potato-calico strain of alfalfa-mosaic virus. Differing from the type by inducing a more severe disease in potato, in which it is commonly found in nature. (Price and Black, *Phytopath.*, 30, 1940, 444-447; Dykstra, *ibid.*, 29, 1939, 917-933; Porter, *Potato Assoc. Amer. Proc.*, 18, 1931, 65-69; Hilgardia, 6, 1931, 277-294; 9, 1935, 383-394.)

22. *Marmor tulipae* H. (*loc. cit.*, 52). From New Latin *Tulipa*, generic name of tulip.

Common name: Tulip color-adding virus.

Hosts: *LILIACEAE*—*Tulipa gesneriana* L., garden tulip; *T. eichleri* Regel; *T. greigi* Regel.

Insusceptible species: *AMARYLLIDACEAE*—*Narcissus* sp., narcissus. *IRIDACEAE*—*Iris germanica* L., iris. *LILIACEAE*—*Allium cepa* L., onion. *SOLANACEAE*—*Nicotiana tabacum* L., tobacco.

Geographical distribution: Wherever hybrid tulips are grown.

Induced disease: In tulip, no obvious effect on leaves but dark striping of flower by pigment intensification. Little interference with growth of plant. No intracellular bodies.

Transmission: By hypodermic injections of expressed juice in dilutions to 10<sup>-5</sup>. By aphids, *Myzus persicae* (Sulz.), *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch, *Illinoia solanifolia* Ashm.), *Aphis* (= *Anuraphis*) *tulipae* B. de Fonsc. (on bulbs), and perhaps *Macrosiphum pelargonii* Kalt (*APHIDIDAE*). Not through seeds from diseased plants.

Thermal inactivation: At 65 to 70° C in 10 minutes.

Literature: Hughes, *Ann. Appl. Biol.*, 18, 1931, 16-29; 21, 1934, 112-119; McWhorter, *Phytopath.*, 22, 1932, 998 (Abst.); 25, 1935, 898 (Abst.); *Ann. Appl. Biol.*, 25, 1938, 254-270.

23. *Marmor milte* H. (*loc. cit.*, 53). From Latin *mitis*, mild.

Common name: Lily latent-mosaic virus.

Hosts: *LILIACEAE*—*Lilium amabile*; *L. auratum* Lindl.; *L. canadense* L.; *L. candidum* L.; *L. cernuum*; *L. chalcedonicum* L.; *L. croceum* Chaix; *L. damodottiae*; *L. elegans* Thunb.; *L. formosanum* Stapf.; *L. giganteum*; *L. henryi* Baker; *L. leucanthum*; *L. longiflorum* Thunb.; *L. myriophyllum*; *L. pumilum*; *L. regale* Wils.; *L. sargentiae* Wils.; *L. speciosum* Thunb.; *L. superbum* L.; *L. testaceum* Lindl.; *L. tigrinum* Ker; *L. umbellatum* Hort.; *L. wallacei*; *Tulipa gesneriana* L., garden tulip; *T. clusiana* Vent.; *T. linifolia* Regel.

Insusceptible species: *LILIACEAE*—*Allium cepa* L., onion; *Lilium kansoni* Leichtl. *IRIDACEAE*—*Iris germanica* L., iris. *SOLANACEAE*—*Nicotiana tabacum* L., tobacco.

Geographical distribution: Wherever lilies and tulips are cultivated.

Induced disease: In Easter lily, masked symptoms or systemic chlorotic mottling, in either case without necrotic flecking. In tulip, systemic chlorotic mottling in foliage and flower "breaking" (color removal, except in a few varieties in which color intensification occurs instead). Intracellular bodies characterize invaded tissues.

Transmission. By inoculation of expressed juice (rubbing surface of leaves), in both lily and tulip. By plugging and grafting of dormant bulbs of tulip. By aphids, *Myzus persicae* (Sulz.), *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch), and *Aphis* (= *Anuraphis*) *tulipae* B. de Fonsc. (*APHIDIDAE*). Not through seeds from mosaic *Lilium longiflorum*.

Thermal inactivation: At 65 to 70° C in 10 minutes.

Literature: Atanasoff, *Bull. Soc. Bot. Bulgarie*, 2, 1928, 51-60; Brierley, *Phytopath.*, 29, 1939, 3 (Abst.); 30, 1940, 230-

Infective in dilutions to  $10^{-8}$ . By aphids, *Macrosiphum pisi* Kalt. and *M. solani-solii* Ashm. (= *M. gae* Koch) (*APHIDIDAE*), with incubation periods of about 12 hours before the insects can infect. Not through seeds from diseased plants.

Thermal inactivation: At  $66^{\circ}\text{C}$  in 10 minutes.

Literature: Böning, Forsch. Geb. Pflanzenkr. u. Immun. Pflanzenreich, 4, 1927, 43-111; Johnson and Jones, Jour. Agr. Res., 54, 1937, 629-638; Loring et al., Proc. Soc. Exp. Biol. and Med., 38, 1938, 239-241; Osborn, Phytopath., 25, 1935, 160-177, 28, 1938, 749-754, 923-931; Pierce, Jour. Agr. Res., 51, 1935, 1017-1039; Snyder, Phytopath., 24, 1934, 78-80; Stubbs, *ibid.*, 27, 1937, 212-266.

21 Marmor medicaginis H (loc. cit., 91) From New Latin *Medicago*, generic name of alfalfa (lucerne).

Common name: Alfalfa-mosaic virus.

Hosts: *LEGUMINOSAE*—*Medicago sativa* L., alfalfa (lucerne). *SOLANACEAE*—*Solanum tuberosum* L., potato. Experimentally, also transmissible to many species of dicotyledonous plants (summarized by Price, Am. Jour. Bot., 27, 1910, 530-541) including *CUCURBITACEAE*—*Cucumis sativus* L., cucumber. *COMPOSITAE*—*Zinnia elegans* Jacq., zinnia. *LEGUMINOSAE*—*Phaseolus vulgaris* L., bean, *Trifolium incarnatum* L., crimson clover. *SOLANACEAE*—*Capicum frutescens* L., pepper, *Lycopersicon esculentum* Mill., tomato, *Nicotiana glauca* L., tobacco.

Geographical distribution: United States.

Induced disease: In alfalfa, systemic chlorotic mottling, tending to be masked at times. In bean, (most varieties) small necrotic primary lesions, reddish brown at periphery. No secondary lesions. Some bean varieties show no lesions after inoculation, one of these, Refugee Hogue, possesses two dominant genes either of which will confer this type of resistance. In tobacco, white necrotic

flecks, small rings and arcs on inoculated leaves, later, systemic mottling, followed by production of necrotic oak-leaf patterns; virus content may be low in plants long diseased, especially in summer.

Transmission: By inoculation of expressed juice. By aphids, *Macrosiphum pisi* Kalt. (for typical strain) and *M. solani-solii* Ashm. (for potato-calico strain) (*APHIDIDAE*). Not through seeds from diseased plants.

Immunological relationships: Resistance to superinfection with the type of this virus is conferred by earlier infection with potato-calico virus (now considered a related strain but earlier regarded as distinct), but not by earlier infection with potato-mottle virus, cucumber-mosaic virus, or the Canada streak strain of potato aucuba-mosaic virus.

Thermal inactivation: At  $65$  to  $70^{\circ}\text{C}$  in 10 minutes.

Other properties: Sedimentation constant,  $73.9 \pm 5.2 \times 10^{-11}$  cm per sec. in a unit centrifugal field. Specific volume 0.673. Particles spherical or nearly so. Diameter 16.5 millimicrons, weight  $2.1 \times 10^6$  times hydrogen unit. Isoelectric point about pH 4.6. Inactivated and, more slowly, hydrolyzed by trypsin.

Literature: Black and Price, Phytopath., 59, 1910, 441-447; Louffer and Ross, Jour. Am. Chem. Soc., 62, 1910, 3296-3300; Pierce, Phytopath., 24, 1934, 87-115; Price, Am. Jour. Bot., 27, 1910, 530-541; Ross, Phytopath., 31, 1941, 391-410, 410-420; Wade and Zaunmeyer, Jour. Am. Soc. Agron., 52, 1910, 127-131; Zaunmeyer, Jour. Agr. Res., 59, 1938, 747-772.

Strains: At least one strain of alfalfa-mosaic virus was formerly considered as an independent virus, causing a disease known as calico in potato. It has now been given varietal rank and distinguished from the type, var. *typicum* Black and Price (Phytopath., 59, 1910, 446) by the following name.

21a Marmor medicaginis var. *solanum* Black and Price (Phytopath., 59, 1910,

Other properties: Active after storage 27 days at  $-6^{\circ}\text{C}$ .

Literature: Brandes, Jour. Agr. Res., 19, 1920, 131-138, 517-522; 24, 1923, 247-262; Desai, Current Science, 3, 1935, 18; Forbes and Mills, Phytopath., 33, 1943, 713-718; Ingram and Summers, Jour. Agr. Res., 52, 1936, 879-888; Kunkel, Bull. Exp. Sta. Hawaiian Sugar Planters' Assoc., Bot. Ser., 3, 1924, 115-167; Matz, Jour. Agr. Res., 46, 1933, 821-839; Rafay, Indian Jour. Agr. Science 5, 1935, 663-670; Sein, Jour. Dept. Agr. Porto Rico, 14, 1930, 40-68; Stoneberg, U. S. Dept. Agr., Tech. Bull. 10, 1927; Tate and Vandenberg, Jour. Agr. Res., 59, 1939, 73-79.

26. *Marmor cepae* H. (loc. cit., 66). From Latin *cepa*, onion.

Common name: Onion yellow-dwarf virus.

Host. *LILIACEAE*—*Allium cepa* L., onion (the variety *viviparum* Metz. is symptomless when infected and may serve as an unrecognized reservoir of virus).

Geographical distribution: United States, Germany, Czecho-Slovakia, Russia, New Zealand.

Induced disease: In onion (most varieties), yellow streaks at base of developing leaf, followed by yellowing, crinkling, and flattening of newly formed leaves; leaves prostrate, flower stalks bent, twisted, stunted; plants reduced in size, bulbs small, yield of seeds reduced. A few varieties of onion are relatively tolerant, and the tree-onion, var. *viviparum* is symptomless after infection.

Transmission: By inoculation of expressed juice. By 48 of 51 tested species of aphid, principally *Aphis rumicis* Lann., *A. maidis* Fitch, and *Rhopalosiphum*

Not  
Not

by contaminated soil.

Thermal inactivation. At 75 to 80° C in 10 minutes

Other properties: Virus withstands dilution to  $10^{-4}$ , storage at 29° C for about

100 hours and storage at  $-14^{\circ}\text{C}$  for more than time tested (6 hours), but is inactivated by drying in leaf tissues.

Literature: Andreyeff, Rev. Appl. Mycol., 17, 1938, 575-576; Blattny, Ochrana Rostlin, 10, 1930, 130-138; Bremer, Phytopath. Ent., 26, 1933, 811-816; Henderson, Phytopath., 20, 1930, 115 (Abst.); Iowa State Coll., Research Bull. 188, 1935, 211-255; Melhus et al., Phytopath., 19, 1929, 73-77; Porter, U. S. Dept. Agr., Plant Dis. Rept., 12, 1928, 93; Tate, Iowa State Coll. Jour. Science, 14, 1940, 267-294.

27. *Marmor scillearum* Smith and Brierley (Phytopath., 34, 1944, 503.) From New Latin *Scilleae*, name of tribe in which hosts are classed.

Common name: Ornithogalum-mosaic virus.

Hosts: *LILIACEAE* (of the tribe *Scilleae*)—*Ornithogalum thyrsoides* Jacq.; probably also *Galltonia candicans* Deene.; *Hyacinthus orientalis* L., hyacinth; *Lachenalia* sp.

Insusceptible species: *LILIACEAE* (of the tribe *Scilleae*)—*Muscari botry-*

*caerulea* L., *Campanula*

*alutacea* L., *DACEAE*—*Pancreatium maritimum*; *Zephyranthus* sp. *IRIDACEAE*—*Tritonia crocata* (L.) Ker. *LILIACEAE*—*Agapanthus africanus*; *Allium cepa*, onion; *A. cernuum* Roth.; *A. fistulosum* L.; *A. porrum* L.; *Gloriosa rothschildiana* O'Brien; *Lilium formosanum* Stapf.; and *L. longiflorum*. *SOLANACEAE*—*Nicotiana glauca* L.

Geographical distribution: United States (Oregon; probably also Alabama and presumed to be widespread in plants of the squill tribe, *Scilleae*, of the family *LILIACEAE*).

Y.*, Yearbk., *1930*, 51-102; Hall, *Gard. Chron.*, *93*, 1933, 330-331; Hughes, *Ann. Appl. Biol.*, *21*, 1934, 112-119; McKay and Warner, *Nat. Hort. Mag.*, *12*, 1933, 179-216; McWhorter, *Phytopath.*, *25*, 1935, 898 (Abst.); *Science*, *86*, 1937, 179; *Ann. Appl. Biol.*, *25*, 1938, 254-270; *Science*, *88*, 1938, 411; Ogilvie and Guterman, *Phytopath.*, *19*, 1929, 311-315.

21 Marmor Iridis II. (*loc. cit.*, 55)  
From New Latin *Iris*, generic name of iris

Common name: Iris-mosaic virus

Hosts: IRIDACEAE—*Iris filifolia* Boiss., *I. angustana* Boiss. and Reut., and *I. xiphium* L., bulbous irises; *Iris ricardi* Hort., *I. unguicularis* Poir.; bearded iris, variety William Mohr

Insusceptible species: SOLANA-CEAE—*Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco; *Petunia hybrida* Vilm., petunia LILIA-CEAE—*Tulipa graneriana* L., tulip

Geographical distribution: United States (Washington, Oregon, California), Holland, Bulgaria, France, England

Induced disease: In bulbous irises, dwarfing of plant, chlorotic mottling of foliage, breaking of flowers. Rate of increase in planting stock decreased. Flower breaks usually darker than normal color of flower. Vacuolate intracellular bodies in some affected tissues

Transmission: By injection of freshly extracted juice of diseased plants into internodal tissue. By aphids, *Macrosiphum (= Illinoia) solanifolii* Ashm. and *Myzus persicae* (Sulz.) (APHIDIDAE)

Literature: Brierley and McWhorter, *Jour. Agr. Res.*, *69*, 1936, 621-635

25 Marmor sacchari II (*loc. cit.*, 60)  
From New Latin *Saccharum*, generic

name of sugar cane, from Latin *saccharum*, sugar.

Common name: Sugar-cane mosaic virus.

Hosts: GRAMINEAE—*Saccharum officinarum* L., sugar cane; *Holcus sorghum* L., sorghum; *H. sudanensis* Bailey, Sudan grass; *Brachiaria platyphylla* Nash, *Chaetochloa magna* Scribn., *C. verticillata* Scribn., *Paspalum bosciannum* Fluegge; *Syntherisma sanguinale* Dulac. Experimentally, also *Zea mays* L., corn (maize); *Chaetochloa lutescens* Stuntz; *Echinochloa crusgalli* Beauv.; *Miscanthus sinensis* Anderss., culm; *Panicum dichotomiflorum* Michx., *Pennisetum glaucum* R. Br., pearl millet; *Saccharum narenga* Wall.

Insusceptible species: All tested species other than Gramineae.

Geographical distribution: Originally in Far East, now in nearly all countries where sugar cane is grown; believed still to be absent from Mauritius.

Induced disease: In sugar cane, systemic mottling chlorosis, light areas of pattern elongated, but crossing veins. Occasionally, stem cankers. Regularly, discoloration and necrosis in mature inner stalk tissues. Vacuolate intracellular bodies occur in diseased tissues. Canes sometimes recover, spontaneously losing the virus and becoming susceptible to reinfection.

Transmission: By inoculation of expressed juice (puncture through inoculum into young leaf). By aphids, *Aphis maidis* Fitch, *Carolinaia cyperi* Ainslie, *Hyeloneura setariae* (Thomas), and *Toxoptera graminum* Rond.; not by *Sipha fava* Lortet (APHIDIDAE). Not by *Draculacephala mollipes* (Say) (CICADELLIDAE).

Serological relationships: Specific neutralizing and precipitating antiserum have been demonstrated.

Thermal inactivation: At 53 to 54° C in 10 minutes in leaf tissue.

Gelatin stab: No liquefaction.

Agar slant: Thin, moist, translucent, becoming greenish.

Broth: Turbid, with pellicle, becoming greenish.

Litmus milk: Slightly acid in a month. The litmus is slowly reduced.

Potato: Moist, glistening, spreading, brown.

Indole is formed (trace).

Nitrites are produced from nitrates.

Aerobic, facultative.

Optimum temperature 35°C.

Habitat: Water.

20. *Pseudomonas convexa* Chester. (*Bacillus fluorescens convexus* Wright, Memoirs Nat. Acad. Sci., 7, 1895, 438; Chester, Determinative Bacteriology, 1901, 325.) From Latin, *convexus*, convex, arched.

Short, thick rods, with rounded ends. Motile, possessing a polar flagellum. Gram-negative

Gelatin colonies. Circular, convex, glistening, bright greenish, translucent. The medium becomes blue-green, fluorescent.

Gelatin stab. Light green, raised, glistening surface growth. No liquefaction.

Agar slant: Moist, translucent, glistening, light greenish. The medium assumes a greenish color

Broth: Turbid, becoming greenish

Litmus milk: No coagulation; alkaline.

Potato: Pale brown, spreading.

Indole not formed.

Nitrites not produced from nitrates

Aerobic, facultative.

Optimum temperature 30°C.

Habitat: Water.

21. *Pseudomonas mildenbergii* Bergey et al. (*Der blaue bacillus*, Mildenberg, Cent. nat. Bakt., II Abt., 56, 1923, 309; *Pseudomonas cyanogena* Bergey et al., Manual, 1, 1923, 129; not *Bacillus cyanogenes* Flügge, Die Mikroorgan-

ismen, 1886, 201; not *Pseudomonas cyanogenes* Hammer, Dairy Bact., 1928, 70; Bergey et al., Manual, 3rd ed., 1930, 172) Named for Mildenberg who first isolated this species.

Rods: 0.3 to 0.5 by 1.0 to 3.5 microns, with rounded ends, occurring singly. Motile, possessing polar flagella. Gram-negative.

Gelatin colonies: Circular, lobed, smooth, glistening, slightly raised, steel-blue, entire.

Gelatin stab: No liquefaction.

Agar colonies: Small, circular, yellowish or reddish-yellow, entire, becoming lobed, grayish-green, iridescent. The medium becomes dirty grayish-green.

Agar slant: Smooth, spreading, slimy, glistening, grayish-green to dark green, fluorescent.

Broth: Turbid green, iridescent to opalescent with slimy sediment.

Litmus milk: Not coagulated, blue ring.

Potato: Slimy, glistening, spreading, steel blue.

Indole not formed.

Nitrites not produced from nitrates.

Aerobic, facultative.

Optimum temperature 25°C.

Source: Isolated from air.

2. *Pseudomonas putida* (Trevisan) Migula. (*Bacillus fluorescens putidus* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 288; *Bacillus putidus* Trevisan, Igen. e le specie d. Batteriacee, 1889, 18; Migula, in Engler and Prantl, Die natur. Pflanzenfam., 1, 1a, 1895, 29; *Bacillus fluorescens putridus* (sic) Kruse, in Flügge, Die Mikroorganismen, 2, 1896, 292; *Bacterium putidum* Lehmann and Neumann, Bakt. Diag., 1 Aufl., 2, 1896, 271; *Pseudomonas putrida* (sic) Migula, Syst. d. Bakt., 2, 1900, 912.) It is not clear which spelling should be used. Either is correct. From Latin *putida* or *putrida*, rotten, stinking.

Rods, with rounded ends. Motile,

Induced disease: In *Ornithogalum thyrsoides*, young leaves finely mottled with light and dark green, and becoming more conspicuously mottled with gray or yellow as the leaves mature; flower stalks sometimes boldly marked with light and dark green blotches. In perianth segments, thin longitudinal streaks

Transmission: By inoculation of expressed juice in the presence of fine carborundum powder, with difficulty. By aphids, *Aphis gossypii* Glov., *Macrosiphum lili* Monell, *M. solanifolii* Ashm., and *Myzus persicae* (Sulz.); less efficiently by *Myzus circumflexus* (Buckt.) (*APHIDIDAE*).

*Key to the species of the Miscellaneous Mosaic-Virus Group.*

Many of the following viruses, although described in some detail in the literature, stand in need of reinvestigation to determine additional properties and possible relationships to preceding groups.

I. Affecting species of *MALVACEAE*.

28. *Marmor abutilon*.

II. Affecting species of *CELASTRACEAE*

29. *Marmor euonymi*.

III. Affecting species of *OLEACEAE*

30. *Marmor ligustri*.

IV. Affecting species of *LEGUMINOSAE* (and no. 39, other families also).

31. *Marmor laburni*.

32. *Marmor arachidis*.

33. *Marmor trifolii*.

34. *Marmor pachyrhizi*.

35. *Marmor viciae*.

36. *Marmor repens*.

37. *Marmor fastidiosum*.

38. *Marmor iners*.

39. *Marmor efficiens*.

V. Affecting species of *GRAMINEAE*

40. *Marmor tritici*.

41. *Marmor graminis*.

VI. Affecting species of *MUSACEAE*.

42. *Marmor abaca*.

VII. Affecting species of *PASSIFLORACEAE*

43. *Marmor passiflorae*.

VIII. Affecting species of *ROSACEAE*.

44. *Marmor flaccumfaciens*.

45. *Marmor rosae*.

46. *Marmor teneniferum*.

47. *Marmor mali*.

48. *Marmor fragariae*.

49. *Marmor marginans*.

50. *Marmor rubi*.

51. *Marmor persicae*.

52. *Marmor astri*.

53. *Marmor rubiginosum*.

54. *Marmor cerasi*.

55. *Marmor lineopictum*.

56. *Marmor pallidolimbatus*.

57. *Marmor nerviclavens*.

IX. Affecting species of *VITACEAE*.58. *Marmor viticola*.X. Affecting species of *SANTALACEAE*.59. *Marmor santali*.XI. Affecting species of *CONVOLVULACEAE* and, experimentally, of other families.60. *Marmor secretum*.XII. Affecting species of *GERANIACEAE*.61. *Marmor pelargonii*.XIII. Affecting species of *SOLANACEAE* and in most cases also of other families.62. *Marmor anglicae*.63. *Marmor aevi*.64. *Marmor raphani*.XIV. Affecting species of *PRIMULACEAE*.65. *Marmor primulae*.XV. Affecting species of *MORACEAE*.66. *Marmor caricae*.XVI. Affecting species of *RUTACEAE*.67. *Marmor italicum*.

28. *Marmor abutilon* H. (*loc. cit.*, 50).  
From New Latin *Abutilon*, generic name  
of a host.

Common name: *Abutilon-mosaic virus*

Hosts: *MALVACEAE*—*Abutilon striatum* Dicks. var. *thompsonii* Veitch. Experimentally, also *Abutilon arboreum* Sweet; *A. avicennae* Gaertn.; *A. esculentum* St. Hil.; *A. indicum* Sweet; *A. in-  
eigne* Planch.; *A. megapotamicum* St. Hil. and Naud; *A. regnellii* Miq; *A. sellowianum* Regel; *A. venosum* Lem; *A. vitifolium* Presl.; *Althaea ficifolia* Cav.; *A. officinalis* L.; *A. rosea* Cav.; *Anoda hastata* Cav.; *Kribelia vitifolia* Willd.; *Malva borealis*; *M. crispa*; *M. mauritiana* Mill.; *M. sylvestris* L.; *M. verticillata* L.; *Malvastrum capense* Garcke; *Modiola decumbens* G. Don; *Sida mollis* Herb; *S. napaea* Cav.; *Sidalcea candida* A. Gray.

Insusceptible species: *MALVACEAE*  
—*Althaea taurinensis*; *Sidalcea purpurea*;  
*Sphaeralcea umbellata* G. Don.

Geographical distribution: Germany, France, England, United States; originally obtained from a single variegated seedling found among green plants of *Abutilon striatum* imported from the West Indies in 1868 by Veitch and Sons; subsequently the infected plant was

propagated vegetatively as an ornamental variety.

Induced disease: In *Abutilon*, systemic chlorotic mottling. Recovery occurs if there is persistent removal of affected leaves, suggesting that the virus does not increase in stems. After recovery, plants are susceptible to reinfection.

Transmission: By grafting, except patch-bark-grafting, which is ineffective. Occasionally through seeds from diseased plants. Not by inoculation of expressed juice. No insect vector is known.

Varieties: Distinctive strains have been noted, but not separately named; one isolate originally occurring in *Abutilon darwini* var. *tesclatum*, seems to belong here; it differs from the type principally in severity of induced disease and in ability to infect *Lavatera arborca*.

Literature: Baur, Ber. d. Deutsch. Bot. Gesellsch., 22, 1904, 453-460; 24, 1906, 416-428; 25, 1907, 410-413; K. Preuss. Akad. Wiss., Sitzungsber., 1906, 11-19; Davis, Ann. Missouri Bot. Gard., 18, 1929, 145-226; Hertzsch, Ztschr. f. Bot., 20, 1927, 65-85; Keur, Phytopath., 23, 1933, 20 (Abst.); 24, 1934, 12-13 (Abst.); Bull. Torrey Bot. Club, 61, 1934, 53-70; Landemuth, Gartenflora, 61, 1902, 323-

29. *Marmor euonymi* H (*loc. cit.*, 51).  
From New Latin *Euonymus*, generic name  
of host.

Common name: *Euonymus-mosaic*  
virus

Hosts: CELASTRACEAE—*Euonymus japonica* L f (sometimes written *Euonymus japonicus*) Probably also *E. radicans* Sieb.

Geographical distribution: Germany.

Induced disease: In *Euonymus japonica*, persistent yellowing along veins

Transmission: By grafting.

Literature: Baur, Ber. d. Deutsch Bot. Gesellsch., 26a, 1908, 711-713, Rischkow, Biol. Zentralbl., 47, 1927, 752-764

30. *Marmor ligustri* H (*loc. cit.*, 52)  
From New Latin *Ligustrum*, generic  
name of host, from Latin *ligustrum*,  
ancient name of privet plant.

Common name: *Ligustrum-mosaic*  
virus

Host: OLEACEAE—*Ligustrum vulgare* L., common privet

Geographical distribution: Germany

Induced disease: Systemic chlorotic  
spotting

Transmission: By grafting. Not  
through seeds from diseased plants.

Literature: Baur, Ber. d. Deutsch Bot. Gesellsch., 25, 1907, 410-413

31. *Marmor laburni* H. (*loc. cit.*, 51).  
From generic name of a host plant,  
*Laburnum vulgare*

Common name: *Laburnum-mosaic*  
virus

Hosts: LEGUMINOSAE—*Laburnum vulgare* Griseb. (= *L. anagyroides* Medic), bean tree. Experimentally, also *Cytisus hirsutus* L.

Insusceptible species: LEGUMINOSAE—*Laburnum alpinum* Griseb., *Cytisus purpureus*.

Geographical distribution: Germany

Induced disease: Systemic chlorotic  
variegation.

Transmission: By bark grafts or by

budding. Not through seeds from diseased plants of *Laburnum vulgare*.

Literature: Baur, Ber. d. Deutsch. Bot. Gesellsch., 25, 1907, 410-413

32. *Marmor arachidis* H. (*loc. cit.*, 67)  
From New Latin *Arachis*, generic name  
of peanut

Common name: Peanut-rosette virus  
Host: LEGUMINOSAE—*Arachis hypogaea* L., peanut

Geographical distribution: Union of  
South Africa, Madagascar, Tanganyika  
Territory, Uganda, Senegal, Gambia,  
Sierra Leone, Java.

Induced disease: In peanut, yellowing  
of young leaves, at first with green veins;

leaflets. Seed formation inhibited. An  
abnormal proliferation of tissues.

Transmission: By grafting. By both  
winged and wingless individuals of the  
aphid, *Aphis laburni* Kalt (= *A. leguminosae* Theob.) (APHIDIDAE). Not  
by 13 tested species of leafhoppers. Not  
by inoculation of expressed juice. Not  
through seed from diseased plants. Not  
through soil

Literature: Hayes, Trop. Agr., 9, 1932,  
211-217; McClintock, Science, 45, 1917,  
47-48; Soyer, Publ. Inst. Nat. Étud.  
Agron. Congo Belge, Sér. Sci., 21, 1939,  
23 pages (Rev. Appl. Mycol., 19, 1940,

59-63.

33. *Marmor trifolii* H (*loc. cit.*, 93)

saic virus.

Hosts: LEGUMINOSAE—*Trifolium pratense* L., red clover, *Lathyrus odoratus* L., sweet pea; *Vicia faba* L., broad bean. Experimentally, also *Trifolium hybridum* L., alsike clover, *T. incarnatum* L., crim-

son clover; *T. repens* L., white clover; *Melilotus alba* Desr., white sweet clover; *Pisum sativum* L., pea.

Insusceptible species: **LEGUMINOSAE**—*Phaseolus vulgaris* L., bean; *P. aureus* Roxb., mung bean; *Medicago sativa* L., alfalfa. **SOLANACEAE**—*Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco; *N. glutinosa* L.; *N. langsdorffii* Weinm.; *N. rustica* L.; *N. sylvestris* Spegaz. and Comes; *Solanum tuberosum* L., potato.

Geographical distribution: United States.

Induced disease: In red clover, yellow color along veins, but no mottling. Sometimes small yellow spots in interveinal areas. Little or no stunting. In *Vicia faba*, experimentally, necrotic splotches or rings sometimes at site of inoculation. Clearing of veins followed by appearance of whitish bands along the veins. Stalks discolored, purplish. Diseased plants are stunted and often die back to a point near the base of the stalk, inducing new growth from buds on the stem.

Transmission: By inoculation of expressed juice, using carborundum. By aphid, *Macrosiphum pisi* Kalt. (**APHIDIDAE**), without incubation period and without long retention. Not by aphids, *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch) or *Aphis rumicis* Linn. (**APHIDIDAE**).

Thermal inactivation: At 60° C in 10 minutes.

Literature: Osborn, *Phytopath.*, 27, 1937, 1051-1058; Zaumeyer, *Jour. Agr. Res.*, 56, 1933, 747-772; Zaumeyer and Wade, *Phytopath.*, 27, 1937, 1009-1013.

31. *Marmor pachyrhizi spec. nov.* From New Latin *Pachyrhizis*, generic name of sincamas

Common name: Sincamas-mosaic virus.

Host: **LEGUMINOSAE**—*Pachyrhizis crocus* (L.) Urb., sincamas (yam bean).

Insusceptible species: **LEGUMINOSAE**—*Phaseolus vulgaris* L., bean

Geographical distribution: Philippine Islands.

Induced disease: In sincamas, chlorotic mottling of foliage; in plants infected when young, dwarfing.

Transmission: By inoculation of expressed juice, in the presence of sand as abrasive. Through about 25 percent of the seeds from infected plants. Not through soil, interlacing of roots, or casual contacts of leaves and stems. No insect vector is known.

Literature: Fajardo and Marañon, *Philippine Jour. Science*, 48, 1932, 129-142.

35. *Marmor vignae spec. nov.* From New Latin *Vigna*, generic name of cowpea, from family name of an Italian botanist, Domenico Vigna.

Common name: Cowpea-mosaic virus.

Hosts: **LEGUMINOSAE**—*Vigna sinensis* (L.) Endl., cowpea. Experimentally, also *Phaseolus lunatus* L., lima bean.

Geographical distribution: United States (Arkansas, Oklahoma, Louisiana, Indiana, Georgia, Iowa, Mississippi, Kansas, New Jersey).

Induced disease: In cowpea, clearing of veins followed by chlorotic mottling, slight convex cupping of leaflets, shortened internodes, abortion of flowers, twisting of petioles, delayed maturity. Malformation of leaves, stunting of plants, and reduction of yield more pronounced in some varieties of cowpea than in others.

Transmission: By inoculation of expressed juice, especially in the presence of fine carborundum powder. By aphids, *Macrosiphum solanifolii* Ashm., *M. pisi* Kalt., *Aphis gossypii* Glov. (**APHIDIDAE**); not by various beetles nor by the bean leafhopper, *Empoasca fabae* LeB. (**CICADELLIDAE**). Through 5 percent of seeds from infected cowpea plants.

Thermal inactivation. At 72 to 75° C in 10 minutes.

Other properties: Infectious in dilutions as high as 1:1000 and after 2 days

storage in expressed juice at room temperature, 20 to 25° C.

Literature: Elliott, *Phytopath.*, 11, 1921, 146-148, Gardner, *Indiana Acad. Science Proc.*, 56, 1927, 231-247, 57, 1928, 417, McLean, *Phytopath.*, 51, 1941, 420-430; Smith, *Science*, 60, 1924, 268.

36. *Marmor repens* Johnson (*Phytopath.*, 32, 1942, 114.) From Latin *repens*, unlooked for, in reference to unexpected discovery of this virus as a constituent of a complex formerly regarded as a single virus, so-called "white-clover mosaic virus".

Common name: Pea-wilt virus.

Hosts **LEGUMINOSAE**—*Trifolium repens* L., white clover. Experimentally, also *Lathyrus odoratus* L., *Lens esculenta* Moench.; *Lupinus albus* L., *Medicago lupulina* L., *Melilotus alba* Desr., *Phaseolus aureus* Roxb., mung bean, *P. vulgaris* L., bean, *Pisum sativum* L., pea, *Trifolium hybridum* L., *T. incarnatum* L., *T. pratense* L.; *Vicia faba* L., *V. sativa* L.; *Vigna sinensis* (L.) Endl., cowpea

Insusceptible species **CARYOPHYLLACEAE**—*Stellaria media* (L.) Cyrill **CHENOPODIACEAE**—*Beta vulgaris* L., *Spinacea oleracea* L. **COMPOSITAE**—*Callistephus chinensis* Nees, *Lactuca sativa* L.; *Taraxacum officinale* Weber, *Zinnia elegans* Jacq. **CRUCIFERAE**—*Barbarea vulgaris* R. Br., *Brassica oleracea* L., *Raphanus sativus* L. **CUCURBITACEAE**—*Cucumis sativus* L. **GRAMINEAE**—*Zea mays* L. **LEGUMINOSAE**—*Glycine max* Merr., *Lupinus hirsutus* L., *Medicago sativa* L. **LILIACEAE**—*Lilium formosanum* Stapf **PLANTAGINACEAE**—*Plantago lanceolata* L., *P. major* L. **POLYGONACEAE**—*Rumex acetosella* L. **SCROPHULARIACEAE**—*Antirrhinum majus* L. **SOLANACEAE**—*Datura stramonium* L., *Lycopersicon esculentum* Mill., *Nicotiana glutinosa* L.; *N. rustica* L., *N. sylvestris* Speng. and Comes, *N. tabacum* L., *Solanum nigrum* L.

Geographical distribution: United States (Washington).

Induced disease: In white clover, systemic chlorotic mottling. In pea, experimentally, originally infected leaves wilt and die, remaining attached to the stem by their shriveled petioles; a few adjacent lower leaves may also wilt and die; in most varieties the top foliage remains green, but in two varieties, Alaska and Canada White, it mottles faintly, stems show faint grayish discoloration; plants are retarded in growth and dwarfed. If pea-mottle virus, *Marmor efficiens* Johnson, is also present, a severe streak disease occurs. Intracellular inclusions absent. In mung bean, experimentally, necrotic zonate local lesions. In cowpea, experimentally, brown necrotic local lesions in inoculated primary leaves, diffuse areas of bleaching in uninoculated trifoliate leaves. In bean, experimentally, mild chlorotic mottling except in three varieties that appear insusceptible (varieties Ideal Market, Kentucky Wonder, and Navy Robust).

Transmission: By inoculation of expressed juice. Not by dodder, *Cuscuta campestris* Yunch (**CONVOLVULACEAE**). Not by pea aphid, *Macrosiphum pisum* Kalt (**APHIDIDAE**). No insect vector is known.

Thermal inactivation: At 58 to 60° C in 10 minutes.

Filterability: Passes Berkefeld W filter candle.

Other properties: Infectious in dilution of 1:100,000. Not inactivated by storage in juice of infected plants at about 25° C for one month or by similar storage in dried tissues of infected pea plants.

Literature: Johnson, *Phytopath.*, 32, 1942, 103-116, Pierce, *Jour. Agr. Res.*, 51, 1935, 1017-1039.

37. *Marmor fastidians spec. nov.* From Latin *fastidians*, disdaining, in reference to slight irregularities in the reported host ranges of constituent strains and failure of this virus to infect certain varieties of the pea although it

may utilize many other varieties of this species as host.

Common name: Alsike-clover mosaic virus.

Hosts: *LEGUMINOSAE*—*Trifolium hybridum* L., alsike clover; *Pisum sativum* L., pea (except the varieties Floral, Perfection, and Surprise). Experimentally, also *Crotalaria striata* DC.; *C. retusa* L.; and *C. spectabilis* Roth (the two last-named species are reported to be insusceptible to the type strain of the virus, but susceptible to one or more of the other tested strains); *Lupinus albus* L.; *L. angustifolius* L.; *Medicago sativa* L.; *Melilotus alba* Desr.; *Phaseolus vulgaris* L., bean; *Trifolium incarnatum* L.; *T. pratense* L.; *Vicia faba* L.

Insusceptible species: *SOLANACEAE*—*Datura stramonium* L.; *Nicotiana glauca* Graham; *N. glutinosa* L.; *N. tabacum* L.; *Petunia hybrida* Wilm. *LEGUMINOSAE*—*Phaseolus aureus* Roxb., mung bean; *P. lunatus* L., sieva bean; *Soja max* (L.) Piper, soybean; *Trifolium repens* L., white clover; *Vicia sativa* L., spring vetch.

Induced disease: In pea and bean, experimentally, systemic chlorotic mottling; some isolates kill inoculated leaves and even cause death of infected plants.

Transmission. By inoculation with expressed juice, at dilutions to 1:6000 or 1:8000. No insect vector is known.

Thermal inactivation. At 60 to 65° C in 10 minutes; one strain at lower temperature, 54 to 58° C.

Strains. Several strains have been distinguished by the severity of their effects on host plants. These may be characterized as follows: var. *fastidiens*, var. *nov.*, type variety, the first of the strains to be described (originally known as alsike clover mosaic virus 1), induces mild disease in pea, does not infect red clover; var. *mitis*, var. *nov.*, described as pea mosaic virus 4, induces mild symptoms on pea, infects red clover; var. *reprimens*, var. *nov.*, described as pea mosaic virus 5, stunts peas severely; var. *denudans*, var. *nov.*, described as alsike clover mosaic

virus 2, defoliates pea plants. Varietal names from New Latin *fastidiens*, epithet of the species, and from Latin *mitis*, mild; *reprimere*, to restrain; and *denudare*, to denude; all three in reference to induced symptoms.

Literature: Wade and Zaumeyer, *Phytopath.*, 28, 1938, 505-511; Zaumeyer, *Jour. Agr. Res.*, 60, 1940, 433-452.

38. *Marmor iners spec. nov.* From Latin *iners*, sluggish or inert, in reference to failure of the virus to spread systemically in certain of its hosts.

Common name: Pea-streak virus.

Hosts: *LEGUMINOSAE*—*Pisum sativum* L., pea. Experimentally, also

*Desf.*; *Lupinus angustifolius* L., blue lupin; *L. luteus* L., yellow lupin; *L. mutabilis* Sweet; *Phaseolus vulgaris* L., bean; *Trifolium arvense* L., haresfoot trefoil; *T. cernuum* Brot., nodding clover; *T. fragiferum* L., strawberry clover; *T. glomeratum* L., cluster clover; *T. hybridum* L., alsike clover; *T. pratense* L., red clover; *T. repens* L., white clover; *Vicia villosa* Roth., hairy vetch. *CUCURBITACEAE*—*Cucumis melo* L., rock melon; *C. sativus* L., cucumber; *Cucurbita pepo* L., marrow.

Insusceptible species: *CHENOPODIACEAE*—*Spinacia oleracea* L., spinach, *Beta vulgaris* L., beet. *COMPOSITAE*—*Calendula officinalis* L., calendula; *Lactuca sativa* L., lettuce; *Zinnia elegans* Jacq., zinnia. *CRUCIFERAE*—*Brassica napus* L., swede; *B. oleracea* L., cabbage; *B. rapa* L., turnip; *Matthiola incana* R. Br., stock; *Raphanus sativus* L., radish, *Sisymbrium officinale* (L.) Scop., hedge mustard. *LEGUMINOSAE*—*Arachis hypogaea* L., peanut; *Lathyrus latifolius* L., perennial sweet pea; *L. pubescens* Hook. and Arn., Argentine sweet pea; *Lotus corniculatus* L.; *Lupinus arboreus* Sims, tree lupin; *Medicago arabica* Huds.; *M. sativa* L., lucerne (alfalfa); *Phaseolus multiflorus* Willd., ran-

*lanecolata* L.; *P. major* L. **POLYGONACEAE**—*Rumex acetosella* L. **SOLANACEAE**—*Datura stramonium* L.; *Lycopersicon esculentum* Mill.; *Nicotiana glutinosa* L.; *N. rustica* L.; *N. sylvestris* Spegaz. and Comes; *N. tabacum* L.; *Solanum nigrum* L.

Geographical distribution: United States (Washington).

Induced disease: Experimentally, in pea, developing leaves late in opening; clearing of veins, chlorotic spotting, stunting, chlorotic mottling; stipules mottled; stems, pods, and seeds appear normal. If pea-wilt virus (*Marmor repens* Johnson) is also present, a severe streak disease occurs. Intracellular inclusions absent. In bean, light yellow spots and clearing of veins. In spinach, severe chlorotic mottling, dwarfing. In alfalfa, streaks of yellowing along veins, chlorotic mottling.

Transmission: By inoculation of expressed juice. By dodder, *Cuscuta campestris* Yunck. (**CONVOLVULACEAE**). Not by pea aphid, *Macrosiphum pisi* Kalt. (**APHIDIDAE**). No insect vector is known.

Thermal inactivation: At 60 to 62° C in 10 minutes.

Filterability: Passes Berkefeld W filter candle.

Other properties: Infectious in dilution of 1:10,000 and after storage in expressed juice or dried tissues for one month at about 25° C.

Literature: Johnson, *Phytopath.*, 32, 1942, 103-116; Johnson and Jones, *Jour. Agr. Res.*, 54, 1937, 629-633, Pierce, *ibid.*, 51, 1935, 1017-1039; Zaumeyer and Wade, *ibid.*, 51, 1935, 715-749.

40. *Marmor tritici* H. (*loc. cit.*, 61). From Latin *tritium*, wheat.

Common names: Wheat-mosaic virus, wheat-rossette virus.

Hosts: **GRAMINEAE**—*Triticum aestivum* L., wheat, *Secale cereale* L., rye. Experimentally, also all tested species of the tribe *Hordeae*; *Triticum compactum* Host; *T. turgidum* L.; *T. durum* Desf.;

*T. dicoccum* Schrank; *T. spelta* L.; *T. polonicum* L.; *T. monococcum* L., *Hordeum vulgare* L., barley.

Insusceptible species: **GRAMINEAE**—*Bromus inermis* Leyss., awnless brome-grass (of the tribe *Festuceae*).

Geographical distribution: United States, Japan.

Induced disease: In wheat, systemic chlorotic mottling, with dwarfing in some varieties; vacuolate, rounded intracellular bodies in diseased cells, usually close to nucleus. Some selections of Harvest Queen wheat are resistant.

Transmission: Through soil, remains infectious in soil 6 or more years. By inoculation of expressed juice (needle punctures in stem). Not through seeds or stubble of diseased plants. No insect vector is known.

Thermal inactivation: Contaminated soil becomes incapable of infecting wheat plants if heated for 10 minutes at 60° C though not if heated for the same length of time at 50° C.

Literature: Johnson, *Science*, 95, 1942, 610; McKinney, *Jour. Agr. Res.*, 23, 1923, 771-800; U. S. Dept. Agr., *Bull.* 1361, 1925; U. S. Dept. Agr., *Circ.* 442, 1937; *Jour. Agr. Res.*, 40, 1930, 547-558; McKinney et al., *ibid.*, 26, 1923, 605-608; Wada and Hukano, *Agr. and Hort.*, 2, 1934, 1778-1790 (*Rev. Appl. Mycol.*, 14, 1935, 618, *Abst.*); *Jour. Imp. Agr. Exp. Sta.*, 3, 1937, 93-123 (*Rev. Appl. Mycol.*, 16, 1937, 665, *Abst.*); Webb, *Jour. Agr. Res.*, 35, 1927, 537-614; 36, 1928, 53-75.

41 *Marmor graminis* McKinney. (*Jour. Washington Acad. Sci.*, 34, 1944, 325) From Latin *gramen*, grass.

Common name: Brome-grass mosaic virus.

Hosts: **GRAMINEAE**—*Bromus inermis* Leyss., awnless brome-grass. Experimentally, also *Triticum aestivum* L., wheat; *Avena sativa* L., oat.

Geographical distribution: United States (Kansas).

Induced disease: In awnless brome-grass, systemic chlorotic mottling of the

type commonly called yellow mosaic because of the distinctly yellow color of the chlorotic areas in affected leaves.

**Transmission:** By inoculation of expressed juice or of aqueous suspensions of dried diseased tissues; not inactivated by drying in diseased tissues for at least 51 days. No insect vector is known.

**Literature:** McKinney et al., *Phytopath.*, 32, 1942, 331.

42. *Marmor abaca* H. (*loc. cit.*, 63). From common name of host plant.

**Common name:** Abacá bunchy-top virus.

**Host** *MUSACEAE*—*Musa textilis* Née, abacá (Manila hemp plant).

**Insusceptible species:** *MUSACEAE*—*Musa sapientum* L. vars. *cinerea* (Blanco) Teodoro, *compressa* (Blanco) Teodoro, *lacatan* (Blanco) Teodoro, and *suaveolens* (Blanco) Teodoro, *M. catenensis* Lamb.

**Geographical distribution:** Philippine Islands.

**Induced disease** In abacá (Manila hemp plant), chlorotic lines and spots along veins of young leaves, followed by growth of distorted leaves, successively shorter, narrower, stiffer, and more curled along their margins. The green areas of mottled leaves, petioles, and leaf sheaths are darker than normal. Newly formed diseased leaves unfurl early, but are short, producing the bunchy top that is referred to in the common name of the disease.

**Transmission** By the aphid, *Pentalonia nigronervosa* Coq. (*APHIDI-DAE*), vector also of the apparently distinct banana bunchy-top virus of Australia. The incubation period of abacá bunchy-top virus in this aphid is between 21 and 45 hours in length. The progeny of viruliferous aphids do not receive the virus directly, but must feed on diseased plants before they can infect healthy abacá. **Transmission** by inoculation of expressed juice has not been demonstrated. No soil transmission.

**Literature.** Oefeleus, *Am. Jour. Bot.*,

17, 1930, 1-18; Philippine Agriculturist, 22, 1934, 567-581.

43. *Marmor passiflorae* H. (*loc. cit.*, 77). From New Latin *Passiflora*, generic name of passion fruit.

**Common name:** Passion-fruit woodiness virus.

**Hosts:** *PASSIFLORACEAE*—*Passiflora edulis* Sims, passion fruit; *P. coerulea* L. Experimentally, also *P. alba* Link and Otto.

**Insusceptible species:** *SOLANACEAE*—*Datura stramonium* L.; *Lycopersicon esculentum* Mill., tomato; *Nicotiana glutinosa* L.; *N. tabacum* L., tobacco.

**Geographical distribution:** Australia (New South Wales, Queensland, Victoria), Kenya.

**Induced disease** In passion fruit, growth checked; leaves puckered, slightly chlorotic or obscurely mottled, curled, twisted, deformed. Clearing of veins has been observed. Color of stems darker green than normal in some places. Fruits short or deformed, discolored, surface sometimes roughened by cracks; so hard as not to be cut through readily. Pericarp or rind of fruit abnormally thick. Pulp deficient, color deepened. At temperatures below 80° F, some abscission of young chlorotic leaves; above 85° F, masking of the disease in most plants.

**Transmission** By inserting cotton in stem wound after soaking it in expressed juice of diseased plant. By aphids, *Myzus persicae* (Sulz.), *Macrosiphum solanifolia* Ashm., and two dark-colored species of the genus *Aphis* (*APHIDIIDAE*).

**Literature** Cobb, *Agr. Gaz. New South Wales*, 12, 1901, 407-418, Noble, *Jour. and Proc. Roy. Soc. New South Wales*, 62, 1928, 79-98, Noble and Noble, *ibid.*, 72, 1930, 293-317; Simmonds, *Queensland Agr. Jour.*, 45, 1936, 322-330.

44. *Marmor flaccumfaciens* H. (*loc. cit.*, 73). From Latin *flaccus*, flabby, and *facere*, to make.

**Common names:** Rose-wilt virus, rose dieback virus.

Hosts: *ROSACEAE*—*Rosa* hybrids, roses.

Geographical distribution: Australia, especially Victoria; New Zealand; possibly Italy.

Induced disease: In rose, leaflets crowded, brittle, recurved. Defoliation progresses from tip to base of plant. Tips of branches discolor and die back an inch or two. Stem darkens at base. Buds remain green and begin development, but growth is soon checked by necrosis at tips. Plant may recover temporarily, but not permanently.

Transmission: By inoculation of expressed juice (needle-puncture and scratch methods). No insect vector is known.

Filterability: Passes Seitz filter (Seitz EK Schichten type, size 6).

Literature: Gigante, Boll. Staz. Pat. Veg. Roma, n. s. 16, 1936, 76-91; Grieve, Austral. Jour. Exp. Biol. and Med. Science, 8, 1931, 107-121; Jour. Dept. Agr. Victoria, 1932 and 1933, pages 30-32.

45. *Marmor rosae* H. (*loc. cit.*, 74). From Latin *rosa*, rose.

Common name: Rose-mosaic virus.

Hosts *ROSACEAE*—*Rosa rugosa* Thunb.; *R. chinensis* Jacq. var. *manetti* Dipp.; *R. multiflora* Thunb.; *R. odorata* Sweet, tea rose; *R. gymnocarpa*; *Rubus parviflorus* Nutt.

Geographical distribution: United States, England, Bulgaria, Brazil.

Induced disease: In *Rosa rugosa* and *R. chinensis* var. *manetti*, systemic chlorotic mottling.

Transmission: By budding and other forms of graftage. Not by inoculation of expressed juice. No insect vector is known.

Literature: Baker and Thomas, Phytopath., 32, 1942, 321-326; Brierley, Phytopath., 25, 1935, 8 (Abst.); Brierley and Smith, Am. Nurseryman, 72, 1940, 5-8; Jour. Agr. Res., 61, 1940, 625-660; Kramer, Revista de Agricultura, 15, 1940, 301-311; O Biologico, 6, 1940, 365-368; McWhorter, U. S. Dept. Agr., Plant Dis. Rep., 15,

1931, 1-3; Milbrath, West. Florist, 13, 1930, 29-30; Nelson, Phytopath., 20, 1930, 130 (Abst.); Newton, Rep. Dom. Bot., 1930, Div. Bot., Canad. Dept. Agr., 1931, 23; Thomas and Massey, Hilgardia, 12, 1939, 645-663; Vibert, Jour. Soc. Imp. et Cent. Hort., 9, 1863, 144-145; White, Phytopath., 22, 1932, 53-60; 24, 1934, 1121-1123.

46. *Marmor veneniferum* H. (*loc. cit.*, 75). From Latin *venenifer*, poisonous, in reference to occasional killing of tissues near inserted bud in graft transmission.

Common name: Rose-streak virus.

Hosts: *ROSACEAE*—*Rosa multiflora* Thunb.; *R. odorata* Sweet; *Rosa* hybrids.

Geographical distribution: Eastern United States.

Induced disease: In various rose species and hybrids, brownish or reddish ring and veinbanding patterns on leaves, and ring patterns on stems. Sometimes necrotic areas near inserted bud, causing girdling of stem and wilting of foliage.

Transmission: By grafting. Not by inoculation of expressed juice. No insect vector is known.

Literature: Brierley, Phytopath., 25, 1935, 7-8 (Abst.); Brierley and Smith, Jour. Agr. Res., 61, 1940, 625-660.

47. *Marmor mali* H. (*loc. cit.*, 75). From Latin *malus*, apple tree.

Common name: Apple-mosaic virus.

Hosts: *ROSACEAE*—*Pyrus malus* L., apple. Experimentally, also *Cotoneaster harrobianus*; *Eriobotrya japonica* Lindl., loquat; *Photinia arbutifolia* Lindl., toyon; *Rosa* sp., rose; *Sorbus pallescens*.

Insusceptible species: *ROSACEAE*—*Amelanchier alnifolia* Nutt.; *Crataegus douglasii* Lindl.; *Pyrus communis* L., pear.

Geographical distribution: United States, Australia, Bulgaria, British Isles.

Induced disease: In apple, clearing of veins and systemic chlorotic spotting. The chlorotic areas sometimes become necrotic during months of intense sunlight.

Transmission: By grafting. No insect

possessing polar flagella. Gram-negative.

Gelatin colonies Small, finely granular, fluorescent with dark center, surrounded by a yellow zone, with pale gray margin.

Source: Isolation stab: Dirty-white surface becoming greenish, fluorescent reaction.

17 *Pseudomonas chloronies*: Circular, raised, smooth, and Frankland) Levine and Frankland) (Bacillus chloronies G and P. periphery.

Plumbea Truss Roy. Soc. Lond. ent. 1874, 714, Bacillus chloronies 1, fluorescent

Syst. d. Bakt., 4, 1900, 471, Lev. Unchanged.

Soppehnd, Bul. No. 77, Iowa State Univ. to brownish, slimy cultural College, 1936) From G. chloronies, greenish yellow.

Rods 0.5 by 1.5 micron, occurring singly and in short chains. Non motile. Gram negative. Grown from nitrates.

Gelatin stab Crateriform liquefaction. 25°C Will grow with green fluorescence. Penn Agr. Exp. sediment

Agar colonies Circular, raised, smooth, amorphous, entire, becoming greenish yellow.

Agar slant Slightly raised, glistening, the medium becoming light greenish yellow.

Broth Moderate turbidity. Dirty yellow sediment. No pellicle.

Litmus milk: Peptonized. Litmus reduced.

Potato Scant, olive green growth. Indole formed.

Nitrates produced from nitrates. Starch hydrolyzed.

Blood serum liquefied in 5 days. Acid from glucose.

Aerobic, facultative. Optimum temperature 22°C. Source: Air.

18 *Pseudomonas oleovorans* Lee and Chandler. (Jour. Bact., 41, 1941, 355) From M. L. oil destroying.

Short rods 0.5 by 0.8 to 1.5 microns, occurring singly and in pairs. Motile. Gram negative. Gelatin stab No liquefaction after 4 weeks.

Litmus milk: Not coagulated.

Potato: Glistening, reddish-brown growth.

Indole not formed.

Nitrites produced from nitrates.

Aerobic, facultative.

Optimum temperature 20°C.

Distinctive characters: Resembles *Pseudomonas viscosa* Migula.

Source: Found in water and soils in Kent, England.

Habitat: Water and soil.

24. *Pseudomonas ovalis* Chester. (*Bacillus fluorescens ovalis* Ravenel, Memoirs Nat. Acad. Sci., 8, 1896, 9; Chester, Determinative Bacteriology, 1901, 325; not *Bacillus ovalis* Wright, Memoirs Nat. Acad. Sci., 7, 1895, 435.) From ovum, egg; M. L. oval.

Rods: 0.3 to 0.7 by 0.7 to 1.3 microns, occurring singly. Motile, possessing a single polar flagellum. Gram-negative.

Gelatin colonies: Irregular, lobate, slightly granular.

Gelatin stab: No liquefaction.

Agar colonies: Circular, opaque, entire, greenish fluorescence.

Agar slant: Thick, white, becoming greenish, fluorescent.

Broth: Turbid, with pellicle.

Litmus milk: No coagulation; alkaline.

Potato: Luxuriant, dirty-brown.

Indole not formed.

Nitrites not produced from nitrates.

Starch not hydrolyzed.

Blood serum not liquefied.

Acid from glucose.

Aerobic, facultative

Optimum temperature 25°C.

Habitat: Soil. Has been found in intestinal canal.

25. *Pseudomonas striata* Chester. (*Bacillus striatus viridis* Ravenel, Memoirs Nat. Acad. Sci., 8, 1896, 22; Chester, Determinative Bacteriology, 1901, 325.) From Latin, *stria*, streak, groove.

Slender rods, of variable lengths, stain-

canes remain short and become rosetted.

Transmission: By aphids, principally *Amphorophora rubi* Kalt., but also *A. rubicola* Oestl. and *A. sensorata* Mason (*APHIDIDAE*). Not by inoculation of expressed juice.

Literature: Bennett, Michigan Agr. Exp. Sta., Techn. Bull. 80, 1927; 125, 1932; Cooley, New York Agr. Exp. Sta. (Geneva), Bull. 675, 1936; Harris, Jour. Pom. and Hort. Science, 11, 1933, 237-255; 17, 1940, 318-343; Rankin, New York Agr. Exp. Sta., Geneva, Bull. 543, 1927; New York Agr. Exp. Sta., Geneva, Tech. Bull. 175, 1931.

51. *Marmor persicae* H. (Holmes, loc. cit., 81; *Flavimacula persicae* McKinney, Jour. Washington Acad. Science, 34, 1944, 149.) From New Latin *Persica*, former generic name of peach.

Common name: Peach-mosaic virus.

Hosts: *ROSACEAE*—*Prunus persica* (L.) Batsch, peach and nectarine, all tested varieties. Experimentally, also *P. armeniaca* L., apricot; *P. communis* Fritsch, almond; *P. domestica* L., plum and prune.

Insusceptible species: Attempts to infect sweet and sour cherries have thus far failed.

Geographical distribution: United States (Colorado, California, Utah, Oklahoma, Texas, New Mexico, Arizona).

Induced disease: In peach, short internodes in spring growth, sometimes breaking in flower pattern, chlorotic mottling and distortion of foliage early in season, masking of leaf symptoms or excision of affected areas of leaf lamina in midsummer; fruit small, irregular in shape, unsalable. Some peach varieties are less damaged than others, but all are thought to be equally susceptible to infection, and equally important as reservoirs of virus when infected. In almond, experimentally, symptomless infections; symptoms appear in some apricot and plum varieties when experimentally infected, not in others.

Transmission: By budding and other

methods of grafting. Not by inoculation of expressed juice. Not through soil. No insect vector is known. Not through pollen or seed from diseased plants.

Thermal inactivation: Not demonstrated; virus not inactivated by temperatures effective in inactivating peach-yellows virus.

Literature: Bodine, Colorado Agr. Exp. Sta., Bull. 421, 1936; Bodine and Durrell, Phytopath., 31, 1941, 322-333; Cation, *ibid.*, 24, 1934, 1380-1381; Christoff, Phytopath. Ztschr., 11, 1938, 360-422; Cochran, California Cultivator, 87, 1940, 164-165; Cochran and Hutchins, Phytopath., 28, 1938, 890-892; Hutchins, Science, 76, 1932, 123; Hutchins et al., U. S. Dept. Agr., Circ. 427, 1937, 48 pp.; Kunkel, Am. Jour. Bot., 23, 1936, 683-686; Phytopath., 28, 1938, 491-497; Thomas and Rawlins, Hilgardia, 12, 1939, 623-644; Valleau, Kentucky Agr. Exp. Sta., Bull. 327, 1932, 89-103.

52. *Marmor astri* H. (loc. cit., 83). From Latin *astrum*, star.

Common name: Peach asteroid-spot virus.

Host: *ROSACEAE*—*Prunus persica* (L.) Batsch, peach.

Geographical distribution: California.

Induced disease: In peach, discrete chlorotic lesions spreading along veins, forming star-like spots; developing leaves normal in appearance, becoming affected as they mature. Some chlorophyll retained in lesions as leaves turn yellow. Affected leaves shed early.

Transmission: By grafting. Not by inoculation of expressed juice. No insect vector is known.

Literature: Cochran and Smith, Phytopath., 28, 1938, 278-281.

53. *Marmor rubiginosum* Reeves. (Phytopath., 30, 1940, 789.) From Latin *rubiginosus*, rusty.

Common name: Cherry rusty-mottle virus.

Host: *ROSACEAE*—*Prunus avium* L., sweet cherry.

vector is known. Transmission by inoculation of expressed juice has not been demonstrated.

Thermal inactivation: Not demonstrated. Virus in stem tissues withstands at least 50° C for as much as 60 minutes without being inactivated.

Literature: Blodgett, *Phytopath.*, 28, 1938, 937-938; Bradford and Joley, *Jour. Agr. Res.*, 46, 1933, 901-908; Christoff, *Phytopath. Zeitschr.*, 7, 1934, 521-536; 8, 1935, 285-296; Thomas, *Hilgardia*, 10, 1937, 581-588.

48 *Marmor fragariae* H. (*loc. cit.*, 78) From New Latin *Fragaria*, generic name of strawberry, from Latin *fraga*, strawberries.

Common name. Strawberry-erinkle virus

Hosts. *ROSACEAE*—*Fragaria* hybrids, cultivated strawberries. Experimentally, also *Fragaria vesca* L., woodland strawberry.

Geographical distribution. United States, England.

Induced disease. In cultivated strawberry, crinkling and chlorosis of leaves. At first, minute chlorotic flecks appear in young leaves. These flecks enlarge, and small necrotic spots may appear in their centers. Vein-clearing appears frequently. Affected foliage lighter and less uniformly green than normal. The variety Royal Sovereign may appear normal through carrying this virus.

Transmission. By aphid, *Myzus fragae-folii* Ckll. (= *Capitophorus fragariae* Theob.) (*APHIDIDAE*). By grafting. Not by inoculation of expressed juice.

Literature: Harris, *Ann. Rept. East Malling Res. Sta.* for 1936, 1937, 201-211, 212-221, *ibid.*, for 1937, 1938, 201-202; Harris and Hildebrand, *Canad. Jour. Res.*, C, 15, 1937, 232-280; Ogilvie et al., *Ann. Rept. Long Ashton Res. Sta.* for 1933, 1934, 96-97; Vaughan, *Phytopath.*, 23, 1933, 733-740; Zeller, *Oregon Agr. Exp. Sta., Sta. Bull.* 319, 1933; Zeller and Vaughan, *Phytopath.*, 22, 1932, 700-713.

49. *Marmor marginans* H. (*loc. cit.*, 79). From Latin *marginare*, to provide with a margin.

Common name: Strawberry yellow-edge virus.

Hosts. *ROSACEAE*—*Fragaria* hybrids, strawberries; *Fragaria californica* C. and S., *F. chiloensis* Duch. (symptomless). Experimentally, also *Fragaria vesca* L.; *F. virginiana* Duch. (some clones appear to be immune to infection by runner-inarching).

Geographical distribution. United States, England, France, New Zealand.

Induced disease. In strawberry, plant appears flat with outer zone of leaves more or less normal, central leaves dwarfed, yellow-edged, deficient in red pigmentation. The variety Premier may carry this virus without showing any obvious manifestation of disease.

Transmission. By aphid, *Myzus fragae-folii* Ckll. (*APHIDIDAE*). By grafting. Not by inoculation of expressed juice. Not through seeds from diseased plants.

Literature: Chamberlain, *New Zealand Jour. Agr.*, 49, 1934, 226-231; Harris, *Jour. Pom. and Hort. Science*, 11, 1933, 56-76; Harris and Hildebrand, *Canad. Jour. Res.*, C, 15, 1937, 232-280; Hildebrand, *ibid.*, C, 19, 1911, 223-233; Plakidas, *Phytopath.*, 16, 1926, 423-426; *Jour. Agr. Res.*, 35, 1927, 1057-1090.

50. *Marmor rubi* H. (Holmes, *loc. cit.*, 80, *Puccinia rubi* McKinney, *Jour. Washington Acad. Science*, 34, 1941, 148.) From Latin *rubus*, bramble bush.

Common name. Red-raspberry mosaic virus.

Hosts. *ROSACEAE*—*Rubus idaeus* L., red raspberry; *R. occidentalis* L., black raspberry.

Geographical distribution: United States

Induced disease. In red raspberry, systemic chlorotic mottling, masked at high temperatures of summer. Foliage development delayed in spring. In some varieties, leaf petioles and cane tips die,

chlorotic bands surrounding discolored areas on leaves. In Mazzard cherry, dwarfing of whole plant, chlorotic bands on leaves.

Transmission: By budding, even in the absence of survival of inserted buds.

57. *Marmor nerviclarens* Zeller and Evans. (Phytopath., 31, 1941, 467.) From Latin *nervus*, sinew or nerve, and *clarere*, to shine.

Common name: Cherry vein-clearing virus.

Hosts. *ROSACEAE*—*Prunus avium* L., sweet cherry. Perhaps also *P. serrulata* Lindl. and *P. domestica* L., on which symptoms similar to those induced by this virus have been observed.

Geographical distribution: United States (Oregon, Washington).

Induced disease: In sweet cherry, clearing of veins throughout each leaf or only in localized areas. Margins of leaves irregular, most indented where clearing of veins is most conspicuous. Elongated, elliptic, or slot-like perforations occur in some leaves. Affected leaves usually narrow. Enations occur as small blistered proliferations on lower side of main veins. Upper leaf surface silvery by reflected light. By midsummer, leaves droop and appear somewhat wilted; they may fold along the midvein. Internodes short; increased number of buds, spurs, or short branches at nodes, rosetting more pronounced on some branches than on others, mostly at end of year-old wood. In advanced disease, fruits pointed, small, flattened on suture side with swollen ridge along suture. Blossoms abnormally abundant, crop of fruit reduced or wanting.

Transmission: By grafting. Not demonstrated by inoculation of expressed juice. No insect vector is known.

58. *Marmor viticola* H. (loc. cit., 83). From Latin *vitis*, vine, and *-cola*, inhabitant of.

Common name: Vine-mosaic virus.

Host: *VITACEAE*—*Vitis vinifera* L., grape.

Geographical distribution: France, Italy, Bulgaria, Czechoslovakia.

Induced disease: In grape, various modifications of systemic chlorotic mottling, and red pigmentation of parts of leaves with subsequent drying and dropping out of affected spots. Leaves deformed, crimped between main veins. Growth restricted.

Transmission: By inoculation of expressed juice and by pruning.

Literature: Blatný, Vínafský obzor., 25, 1931, 4-5 (Cent. f. Bakt., II Abt., 84, 1931, 464); Ochrana Rostlin, 13, 1933, 104-105 (Rev. Appl. Mycol., 13, 1934, 421); Gigante, Boll. Staz. Pat. Veg. Roma, n. s. 17, 1937, 169-192 (Rev. Appl. Mycol., 17, 1938, 221); Pantanelli, Malpighia, 24, 1911, 497-523; 25, 1912, 17-46; Stranák, II Congr. Intern. Path. Comp. Paris, 1931, 367-378; Ochrana Rostlin, 11, 1931, 89-98 (Rev. Appl. Mycol., 11, 1932, 230); Vielwerth, Ochrana Rostlin, 15, 1933, 83-90 (Rev. Appl. Mycol., 13, 1934, 421-422).

59. *Marmor santali* H. (loc. cit., 94). From New Latin, *Santalum*, generic name of sandal.

Common name: Sandal leaf-curl virus.

Host. *SANTALACEAE*—*Santalum album* L., sandal.

Geographical distribution: India.

Induced disease: In sandal, leaves small, curled, wrinkled, thickened, brittle, abscising. Systemic chlorotic mottling. Internode length normal. Infected twigs produce both flowers and fruits.

Transmission: By ring bark-graft. Not by inoculation of expressed juice. No insect vector is known.

Literature: Venkata Rao, Mysore Sandal Spike Invest. Comm., Bull. 3, 1933.

60. *Marmor secretum* Bennett. (Phytopath., 34, 1944, 88). From Latin *secretus*, hidden.

Common name: Dodder latent-mosaic virus.

Hosts: *CONVOLVULACEAE*—*Erythraea californica* Choisy, dodder. Experi-

Geographical distribution: United States (Washington).

Induced disease: In sweet cherry, chlorotic mottling 4 to 5 weeks after full bloom, first on small basal leaves, later on all leaves. The older affected leaves develop autumnal colors and absciss, 30 to 70 per cent of the foliage being lost. The remaining foliage appears somewhat wilted, shows increased mottling, chlorotic spots, and areas becoming yellowish brown, appearing rusty. Blossoms normal. Fruits smaller than normal, insipid, not misshapen. Growth rate of tree reduced slightly.

Transmission. By grafting. Not by inoculation of expressed juice. No insect vector is known.

Literature. Reeves, *Phytopath.*, 30, 1910, 789 (Abst.); *Jour. Agr. Res.*, 62, 1911, 555-572 (see 566-567).

54 Marmor cerasi Zeller and Evans. (*Phytopath.*, 31, 1911, 467.) From Latin *cerasus*, cherry tree; originally spelled *cerasae*, by error

Common name. Cherry mottle-leaf virus.

Hosts. *ROSACEAE*—*Prunus arum* L., sweet cherry, *P. emarginata* (Dougl.) Walp., wild cherry. Experimentally, also *P. cerasus* L. (tolerant) and *P. mahaleb* L. (tolerant).

Geographical distribution. United States (Washington, Oregon, Idaho, California) and Canada (British Columbia).

Induced disease. In sweet cherry, chlorotic mottling, leaves puckered, wrinkled, distorted, not perforated. Blossoms not affected. Fruit small, hard, insipid, uneven or delayed in ripening. Crop reduced. Branches shortened, tree eventually stunted.

Transmission. By budding. No insect vector is known. Not by the black cherry aphid, *Myzus cerasi* (F.) (*APHIDIDAE*). Not by inoculation of expressed juice.

Thermal inactivation. Not demonstrated, not at 46° C in 60 minutes nor at 19° C in 10 minutes in bud sticks.

Literature: Reeves, Washington State Hort. Assoc. Proc., 31, 1935, 85-89; *Jour. Agr. Res.*, 62, 1911, 555-572; Zeller, Oregon State Hort. Soc. Report, 26, 1934, 92-95; *Phytopath.*, 31, 1911, 463-467.

55 Marmor lineopictum Cation (*Phytopath.*, 31, 1911, 1009.) From Latin *linea*, line, and *pictus*, ornamented.

Common names: *Prunus* line-pattern virus, peach line-pattern virus.

Hosts. *ROSACEAE*—*Prunus salicina* Lindl., Japanese plum, *P. mahaleb* L., Mahaleb cherry; *P. persica* (L.) Batsch, peach (= *Amygdalus persica* L.).

Geographical distribution: United States (Kentucky, Michigan, California, Ohio; perhaps widely distributed).

Induced disease. In peach and Mahaleb cherry, light-colored line patterns or faint chlorotic mottling, tending to become masked as leaf becomes old. In peach, affected foliage sometimes less glossy than normal. In *Prunus salicina*, no disease manifestations usually, rarely, chlorotic mottling on a few leaves.

Transmission. By grafting. No insect vector is known.

Literature. Berkeley, Div. of Bot. and Plant Path., Science Service, Dominion Dept. Agr., Ottawa, Canada, Publ. 679, 1911; Cation, *Phytopath.*, 31, 1911, 1001-1010, Thomas and Rawlins, *Hilgardia*, 12, 1939, 623-644; Valleau, Kentucky Agr. Exp. Sta., Res. Bull. 327, 1932, 89-103.

56. Marmor pallidolimbatus Zeller and Milbrath. (In Handbook of Virus Diseases of Stone Fruits in North America, Michigan Agr. Exp. Sta., Miscell. Publ., May, 1942, 50, *Phytopath.*, 32, 1912, 635.) From Latin *pallidus*, pale, and *limbatus*, bordered.

Common name. Cherry banded-chlorosis virus.

Hosts: *ROSACEAE*—*Prunus serrulata* Lindl., flowering cherry; *P. arum* L., Mazzard cherry.

Geographical distribution: United States (Pacific Northwest).

Induced disease: In flowering cherry,

Laubert, Gartenwelt, 31, 1927, 391; Pape, *ibid.*, 26, 1927, 329-331; 32, 1928, 116-117; Pethybridge and Smith, Gard. Chron., 92, 1932, 378-379; Schmidt, Gartenwelt, 81, 1932, 40; Seeliger, Nachrichtenbl. Deutsch. Pflanzenschutzdienst, 6, 1926, 63-64; Tuimann, Gartenwelt, 31, 1927, 375-376; Verplancke, Bul. Cl. Sci. Acad. Roy. de Belgique, Ser. 5, 18, 1932, 269-281 (Rev. Appl. Mycol., 11, 1932, 649-650).

62. *Marmor angliae* H. (*loc. cit.*, 48). From Latin *Anglia*, England.

Common name: Potato-paracriable virus.

Hosts: *SOLANACEAE*—*Solanum tuberosum* L., potato. Experimentally, also *Datura stramonium* L., Jimson weed.

Insusceptible species: *SOLANACEAE*—*Nicotiana tabacum* L., tobacco.

Geographical distribution: England.

Induced disease: In potato, masked in all plants of the variety King Edward. Chlorotic mottling with some necrosis in the varieties Arran Victory and Arran Chief. Chlorotic mottling only in Arran Comrade, Majestic, and Great Scot potatoes. Two varieties, Sharpe's Express and Epicure, are said to be resistant.

Transmission: By grafts. Not by inoculation of expressed juice. No insect vector is known.

Literature: Dykstra, Phytopath., 26, 1936, 597-606; Salaman and Le Pelley, Proc. Roy. Soc. London, Ser. B, 106, 1930, 140-175.

63. *Marmor aevi* spec. nov. From Latin *aevum*, old age, in reference to the obvious involvement of old, but not of young, delphinium leaves.

Common name: Celery-calico virus.

Hosts: *CUCURBITACEAE*—*Cucumis sativus* L., cucumber; *C. melo* L., cantaloupe; *Cucurbita pepo* L., summer crookneck squash. *RANUNCULACEAE*—*Delphinium chaniensis*; *D. formosum*, hardy larkspur, *D. grandiflorum*; *D. parryi*; *D. zaidi*. *SOLANACEAE*—*Lycopersicon esculentum* Mill., tomato.

*UMBELLIFERAE*—*Apium graveolens* L., celery. Experimentally, also *SOLANACEAE*—*Nicotiana tabacum* L., tobacco; *Petunia hybrida* Vilm., petunia. *VIOLACEAE*—*Viola cornuta* L.

Geographical distribution: United States.

Induced disease: In celery, clearing of veins, puckering and downward cupping of younger leaves, green islands of tissue in lemon-yellow areas of outer leaves, green and yellow zigzag bands on leaflets. In delphinium, basal and middle leaves with pale-orange, amber, or lemon-yellow areas; younger leaves normal green, chlorotic ring and line patterns.

Transmission: By inoculation of expressed juice in the presence of finely powdered carborundum. By aphids: *Aphis apigraveolens* Essig, celery leaf aphid; *A. api* Theob., celery aphid; *A. ferruginea-striata* Essig, rusty-banded aphid; *A. gossypii* Glov., cotton aphid; *A. middletoni* Thomas, erigeron root aphid, *Myzus circumflexus* (Buckt.), lily aphid; *M. convolvuli* (Kalt.), foxglove aphid; *M. persicae* (Sulz.), green peach aphid; *Rhopalosiphum melliferum* (Hottes), honeysuckle aphid (*APHIDIIDAE*).

Literature: Severin, Hilgardia, 14, 1942, 441-461; Severin and Freitag, Phytopath., 25, 1935, 891 (Abst.); Hilgardia, 11, 1938, 493-553.

64. *Marmor raphani* spec. nov. From Latin *raphanus*, radish.

Common name: Radish-mosaic virus.

Hosts: *CRUCIFERAE*—*Raphanus sativus* L., radish. Experimentally, also *CRUCIFERAE*—*Brassica oleracea* L.; *B. nigra* (L.) Koch; *B. alba* (L.) Boiss.; *B. arvensis* (L.) Ktze.; *B. pe-tsai* Bailey; *B. juncea* (L.) Czoss; *B. rapa* L.; *B. adpressa* Boiss., *Capsella bursa-pastoris* (L.) Medic; *Malcomia maritima* R. Br.; *M. bicornis* DC. *CHENOPODIACEAE*—*Chenopodium album* L.; *C. murale* L.; *Spinacia oleracea* L. *RANUNCULACEAE*—*Delphinium ajacis* L. *SOLANACEAE*—*Nicotiana glutinosa* L.; *N.*

mentally, also *CHENOPODIACEAE*—*Beta vulgaris* L., sugar beet; *Chenopodium album* L., lamb's quarters; *C. murale* L., sowbane. *CONVOLVULACEAE*—*Cuscuta campestris* Yunker; *C. subinclusa* Dur. and Hilg. *CRUCIFERAE*—*Brassica incana* (L.) F. W. Schultz, mustard (tolerant). *CUCURBITACEAE*—*Cucumis melo* L., cantaloupe. *PHYTOLACCACEAE*—*Phytolacca americana* L., pokeweed. *PLANTAGINACEAE*—*Plantago major* L., plantain. *POLYGONACEAE*—*Fagopyrum esculentum* Moench, buckwheat; *Polygonum pennsylvanicum* L., knotweed. *PRIMULACEAE*—*Samolus floribundus* HBK., water pimpernel. *SOLANACEAE*—*Lycopersicon esculentum* Mill., tomato, *Nicotiana glauca* Graham (tolerant); *N. palmeri* Gray; *N. rustica* L. (tolerant); *N. tabacum* L. (tolerant); *Solanum tuberosum* L., potato. *UMBELLIFERAE*—*Apium gratiicola* L., celery.

Insusceptible species: *COMPOSITAE*—*Helianthus annuus* L., sunflower; *Lactuca sativa* L., lettuce. *CRUCIFERAE*—*Brassica oleracea* L., cabbage. *POLYGONACEAE*—*Eriogonum fasciculatum* Benth., California buckwheat. *SCROPHULARIACEAE*—*Verbascum thapsus* L., mullein. *SOLANACEAE*—*Atropa belladonna* L., belladonna.

Geographical distribution United States (California).

Induced disease: In dodder, no symptoms. In sugar beet, experimentally, temporary systemic chlorotic spotting; occasional faded areas in leaves in subsequent chronic stage of disease. In cantaloupe, experimentally, chlorotic spotting, reduction in leaf size, death of some leaves, stunting of plant; melons small and of poor quality. In celery, experimentally, systemic chlorosis followed by dwarfing and mottling with subsequent apparent recovery.

Transmission By dodder, *Cuscuta californica*, *C. campestris*, and *C. subinclusa*. By inoculation of extracted juice to some, but not to other, host plants, *Phytolacca americana* is readily infected by rubbing

methods in the presence of a small amount of abrasive, and develops numerous necrotic primary lesions that serve for quantitative estimation of concentration of virus in inoculum. Through seeds from infected plants of dodder, *Cuscuta campestris*; not through seeds from diseased cantaloupe, buckwheat, or pokeweed plants. No insect vector is known.

Thermal inactivation: At 56 to 60° C in 10 minutes.

Filterability: Passes celite and Berkefeld N and W filters.

Other properties: Infective in dilutions to 1:3000. Inactivated by drying and by storage in expressed pokeweed juice, within 48 hours.

61. Marmor pelargonii spec. nov. From New Latin *Pelargonium*, generic name of common geranium.

Common names: Pelargonium leaf-curl virus, virus of droopy or Kräuselkrankheit of geranium.

Host *GERANIACEAE*—*Pelargonium hortorum* Bailey, geranium.

Induced disease In geranium, circular or irregular chlorotic spots, sometimes stellate or dendritic,  $\frac{1}{4}$  to 5 mm in diameter, centers becoming brown with chlorotic border; severely affected leaves become yellow and drop; spotted leaves ruffled, crinkled, malformed, small, sometimes puckered and splitting. Petioles and stems show corky, raised, necrotic streaks; tops may die. Disease most severe in spring, inconspicuous in summer.

Transmission: By grafting. Not by inoculation of expressed juice nor by use of knife to prepare cuttings for propagation. Not through seed. No insect vector is known.

Literature: Berkeley, Canad. Hort. and Home Mag., 1938, 1939, 1-4; Blating, Ochrana Rostlin, 13, 1933, 145 (Rev. Appl. Mycol., 13, 1931, 378-379); Bremer, Blumen-u. Pflanzentau, 48, 1933, 32-33 (Rev. Appl. Mycol., 12, 1933, 514); Halstead, New Jersey Agr. Exp. Sta., Rept. 14, 1933, 432-433; Jones, Washington Agr. Exp. Sta., Bull. 390, 1910;

fig; *F. allissima* Blume; *F. krishna*; and *F. tsicola* Roxb.

Geographical distribution: United States (California, Texas), England, Puerto Rico, China, New South Wales, Western Australia.

Induced disease: In fig, systemic chlorotic spotting and mottling of foliage; some severe leaf distortion. Fruits sometimes affected, bearing light circular areas, rusty spots, being deformed or dropped prematurely. Necrotic lesions on profichi of Samson caprifigs also have been attributed to action of this virus.

Transmission. By budding. No insect vector is known; mites have been suspected as possible vectors.

Literature: Condit and Horne, *Phytopath.*, 23, 1933, 887-896; 31, 1941, 561-563; 33, 1943, 719-723, Ho and Li, *Lingnan Science Jour.*, 15, 1936, 69-70; Pittman, *W. Austral. Dept. Agr. Jour.*, 12, 1935 196.

67. *Marmor italicum* (Fawcett) comb. nov. (*Citrus italicum* Fawcett, *Phytopath.*, 31, 1941, 357.) Specific epithet meaning "pertaining to Italy."

Common name Citrus infectious-mottling virus.

Host: *RUTACEAE*—*Citrus aurantium* L., sour orange.

Geographical distribution: Italy.

Induced disease. In sour orange, white, pale green, or yellow irregular areas in leaves, leaving narrow green bands along midrib; leaves blistered and distorted.

Transmission: The aphid, *Toxoptera aurantii* (Phytopath., 24, 1934, 661), has been suspected as vector.

Literature: Fawcett, *Phytopath.*, 31, 1941, 356-357; Petri, *Bol. Staz. Pat. Veg. Roma, n. s.* 11, 1931, 105-114.

NOTE: Several additional species were described too late for complete systematic treatment here. They are plain's wheat mosaic virus, *Marmor campestris* McKinney (*Jour. Washington Acad. Sci.*, 34, 1944, 324) with varieties *typicum* McKinney and *galbinum* McKinney, respectively causing light-green mosaic and severe yellow mosaic of wheat in Kansas; wheat streak-mosaic virus, *Marmor virgatum* McKinney (*ibid.*, 34, 1944, 324) with varieties *typicum* McKinney and *viride* McKinney (*ibid.*, 34, 1944, 325), respectively causing yellow streak-mosaic and green streak-mosaic of wheat in Kansas; *Agropyron*-mosaic virus, *Marmor agropyri* McKinney (*ibid.*, 34, 1944, 326), with varieties *typicum* McKinney and *flavum* McKinney, respectively causing green-mosaic mottling and yellow-mosaic mottling in the grass *Agropyron repens* (L.) Beauv. in Virginia; also a virus, *Flavimacula ipomoeae* Doolittle and Harter (*Phytopath.*, 33, 1945, 763), causing feathery mottle of sweet potato in Maryland [see *Marmor periscae* for treatment of a virus that was assigned as type of *Flavimacula* McKinney (*Jour. Washington Acad. Sci.*, 34, 1944, 149), a genus originally differentiated from *Marmor* as containing viruses not yet inoculable save by tissue union; a natural group of viruses may be represented but their characteristics and affiliations seem not yet clear].

## Genus 11. *Acrogenus* Holmes.

(*Loc. cit.*, 110.)

Viruses of the Spindle-Tuber Group, inducing diseases characterized by abnormal growth habit of host plants without chlorotic or necrotic spotting, systemic chlorosis, witches'-broom formation, or production of galls. Generic name from Greek, meaning point- or peak-producing, in reference to shape of potatoes affected by potato spindle-tuber virus.

The type species is *Acrogenus solani* Holmes.

*langsdoeffii* Weinm.; *N. rustica* L.; *N. tabacum* L.

Geographical distribution: United States (California).

Induced disease: In radish, systemic chlorotic spotting followed by chlorotic mottling of foliage; little or no leaf distortion; plants not stunted.

Transmission: By inoculation of expressed juice. No insect vector is known, not by the cabbage aphid, *Brevicoryne brassicae* (L.); the false cabbage

seeds from diseased radish plants.

Thermal inactivation: At 65 to 68° C in 10 minutes.

Literature: Tompkins, Jour. Agr. Res., 68, 1939, 119-130.

65. Marmor primulae spec. nov. From New Latin *Primula*, generic name of primrose.

Common name. Primrose-mosaic virus.

Hosts. PRIMULACEAE—*Primula obconica* Hance. Experimentally, also *P. malacoides* Franch and *P. sinensis* Lindl.

Insusceptible species. BEGONIACEAE—*Begonia semperflorens* Link and Otto. BORAGINACEAE—*Myosotis alpestris* Schmidt. CAMPANULACEAE—*Campanula medium* L. CARYOPHYLLACEAE—*Dianthus barbatus* L. CHENOPODIACEAE—*Spinacia oleracea* L. COMPOSITAE—*Bellis perennis* L., *Callistephus chinensis* Nees, *Gerbera jamesonii* Hook., *Lactuca sativa* L., *Senecio cruentus* DC., *Tagetes patula* L. CRUCIFERAE—*Brassica oleracea* L., *B. pekinensis* Bailey, *B. rapa* L., *Matthiola incana* R. Br., *Raphanus sativus* L. CUCURBITACEAE—*Cucumis sativus* L., *Cucurbita pepo* L. EUPHORBIACEAE—*Ricinus communis* L. GRAMINEAE—*Zea mays* L. LEGUMINOSAE—*Pisum sativum* L., *Vicia faba* L., *Vigna sinensis* (Torner) Sims. LO-

BELLACEAE—*Lobelia hybrida* Hort. PAPAVERACEAE—*Papaver orientale*

L. PRIMULACEAE—*Anagallis arvensis* L.; *Cyclamen indicum* L.; *Primula auricula* L.; *P. veris* L. RANUNCULACEAE—*Anemone coronaria* L.; *Delphinium cultorum* Voss; *Ranunculus asiaticus* L. RESEDACEAE—*Reseda odorata* L. ROSACEAE—*Geum chiloense* Balb. SCROPHULARIACEAE—*Antirrhinum majus* L., *Pentstemon barbatus* Nutt. SOLANACEAE—*Capsicum frutescens* L., *Datura stramonium* L.; *Lycopersicon esculentum* Mill.; *Nicotiana glutinosa* L.; *N. tabacum* L., *Solanum tuberosum* L. TROPAEOLACEAE—*Tropaeolum majus* L. UMBELLIFERAE—*Apium graveolens* L. VERBENACEAE—*Verbena hybrida* Voss. VIOLACEAE—*Viola tricolor* L.

Geographical distribution: United States (California).

Induced disease. In *Primula obconica*, chlorosis, stunting, rugosity with upward, or occasionally downward, cupping of leaves. Petioles and peduncles shortened, flowers reduced in size, broken in color (white-streaked). Leaves coarsely mottled with yellow-green, leaving green islands, tips of leaves sometimes narrowed.

Transmission. By inoculation of expressed juice, in the presence of 600 mesh powdered carborundum. Not by aphids, *Myzus persicae* (Sulz.) and *M. circumflexus* (Buekt.) (APHIDIDAE). No insect vector is known. Probably not through seeds.

Thermal inactivation: At 50° C, not 48° C, in 10 minutes.

Other properties. Infective after 21, not 48, hours *in vitro*. Infective after 1:10 dilution.

Literature: Tompkins and Middleton, Jour. Agr. Res., 63, 1911, 671-679.

66. Marmor caricae (Condit and Horne) comb. nov. (*Ficus caricae* Condit and Horne, Phytopath., 31, 1911, 563.) From Latin *carica*, a kind of dried fig.

Common name. Fig-mosaic virus.

Hosts. MORACEAE—*Ficus carica* L.,

ing and rolling of leaves. Foliage leathery. Sometimes conspicuous phloem necrosis. Generic name from Latin *corium*, leather.

The type species is *Corium solani* Holmes.

*Key to the species of genus Corium.*

I. Infecting potato.

II. Infecting beet.

III. Infecting raspberry.

1. *Corium solani*.

2. *Corium betae*.

3. *Corium rubi*.

4. *Corium ruborum*.

1. *Corium solani* Holmes. (Handb. Phytopath. Viruses, 1930, 120.) From New Latin *Solanum*, generic name of potato.

Common name: Potato leaf-roll virus.

Hosts: **SOLANACEAE**—*Solanum tuberosum* L., potato. Experimentally, also other solanaceous species, *Datura stramonium* L., Jimson weed; *Lycopersicon esculentum* Mill., tomato; *Solanum dulcamara* L., bittersweet, *S. villosum*.

Insusceptible species: **CHENOPODIACEAE**—*Beta vulgaris* L., beet.

Geographical distribution: North America, France, British Isles, probably wherever potatoes are grown.

Induced disease In potato, leaves thick, rigid, leathery, and rolled, their starch content excessive. Plants dwarfed. Tubers few, small, crisp. Tubers of some varieties show conspicuous phloem necrosis, germinate with spindling sprouts.

Transmission: By aphid, *Myzus persicae* (Sulz.) (**APHIDIDAE**), with incubation period of 24 to 48 hours. Also by *Myzus convolvuli* (Kalt.) (= *M. pseudo-solani* Theob.), *M. circumflexus* (Buckt.), *Macrosiphum solanifolii* Ashm., and *Aphis abbreviata* Patch (**APHIDIDAE**). By grafting. Not by inoculation of expressed juice.

Literature: Artschwager, Jour. Agr. Res., 16, 1918, 559-570; 24, 1923, 237-245; Dykstra, *ibid.*, 47, 1933, 17-32, Elze, Phytopath., 21, 1931, 675-686, Folsom, Maine Agr. Exp. Sta., Bull. 297, 1921,

37-52; 410, 1942, 215-250; Murphy, Scient. Proc. Roy. Dublin Soc., 17, 1923, 163-184; Murphy and M'Kay, *ibid.*, 19, 1929, 341-353; Schultz and Folsom, Jour. Agr. Res., 21, 1921, 47-80; Smith, Ann. Appl. Biol., 16, 1929, 209-229; 18, 1931, 141-157, Stevenson et al., Am. Potato Jour., 20, 1943, 1-10.

2. *Corium betae* spec. nov. From Latin *beta*, beet.

Common names: Sugar-beet yellows virus, beet-yellows virus, jaunisse virus, vergelingsziekte virus.

Hosts: **CHENOPODIACEAE**—*Beta vulgaris* L., beet; *B. maritima* L.; *B. cicla*; *Atriplex hortensis* L., *A. sibirica* L.; *Chenopodium album* L., lamb's quarters; *Spinacia oleracea* L., spinach. **AMARANTHACEAE**—*Amaranthus retroflexus* L.

Insusceptible species: **SOLANACEAE**—*Solanum tuberosum* L., potato; all other tested solanaceous species.

Geographical distribution: Belgium, Netherlands, Denmark, England; perhaps Germany and the United States.

Induced disease: In beet, young leaves little affected; older leaves yellow, brittle, short, thick, containing excessive amounts of carbohydrates; necrosis in secondary phloem. In spinach, yellowing, necrosis between veins on old leaves.

Transmission: Not by inoculation of expressed juice. By aphids, *Myzus persicae* (Sulz.), *Aphis fabae* Scop., *Macrosiphum solanifolii* Ashm., and *Aulacor-*

*Key to the species of genus Acrogenus.*

## I. Infecting potato.

## II. Infecting black currant.

1. *Acrogenus solani* Holmes. (Handb. Phytopath. Viruses, 1939, 111.) From New Latin *Solanum*, generic name of potato.

Common names: Potato spindle-tuber virus, potato spindling-tuber virus, potato marginal leaf-roll virus.

Host: SOLANACEAE—*Solanum tuberosum* L., potato.

Geographical distribution: United States and Canada.

Induced disease: Plants erect, stiff, spindly, lacking vigor. Leaves small, erect, darker green than normal. Petioles sometimes slender, brittle. Tubers long, cylindrical, irregular in shape, tapered at ends, smooth and tender-skinned, of softer than normal flesh in spring. Eyes of tuber conspicuous.

Transmission: By inoculation of expressed juice, by use of contaminated knife in cutting successive tubers before planting; by contacts of freshly cut seed pieces. By aphids, *Myzus persicae* (Sulz.) and *Macrosiphum solanifolii* Ashm. (= *M. gei* Koch) (APHIDIDAE). Also by certain leaf-eating insects.

Thermal inactivation: At 60 to 65° C in 10 minutes (in tuber tissues).

Literature: Bald et al., *Phytopath.*, 31, 1911, 181-186; Folsom, *Maine Agr. Exp. Sta.*, Orono, Bull. 312, 1923; Goss, *Phytopath.*, 16, 1926, 223, 299-303; 18, 1928, 445-448; *Nebraska Agr. Exp. Sta.*, Res. Bull. 47, 1930, 63, 1931; Jaczewski, *La Défense des Plantes*, Leningrad, 4, 1927, 62-77 (Rev. Appl. Mycol., 6, 1927, 572-573, Abst.); McLeod, *Canad. Exp. Farms, Div. Bot., Rpt.* for 1926, 1927.

1. *Acrogenus solani*.2. *Acrogenus ribis*.

Strains: A strain causing unmottled curly dwarf of potato has been given a varietal name to distinguish it from the type, var. *vulgaris* H. (loc. cit., 111).

1a. *Acrogenus solani* var. *severus* H. (loc. cit., 112). Inducing symptoms in potato on the whole more severe than those caused by the type strain.

Common name: Unmottled curly-dwarf strain of potato spindle-tuber virus. (*Goss, Nebraska Agr. Exp. Sta., Res. Bull.* 47, 1930, 63, 1931; Schultz and Folsom, *Jour. Agr. Res.*, 25, 1923, 43-118.)

2. *Acrogenus ribis* H. (loc. cit., 112). From Latin *ribes*, currant.

Common name: Black-currant reversion-disease virus.

Host: SAXIFRAGACEAE—*Ribes nigrum* L., European black currant.

Geographical distribution: British Isles.

Induced disease: In European black currant, leaves abnormally narrow and flat, small veins few. Flowers sometimes nearly transparent, smooth, sepals brightly colored beneath. Flowers and small fruits fall. Stems less woody than normal, with tendency to excessive gum production.

Transmission: By grafting. By big-bud mite, *Eriophyes ribis* (ERIOPHYIDAE). Not by inoculation of expressed juice. Not through soil. Not through seeds from diseased plants.

Literature: Amos and Hatton, *Jour. Pom. and Hort. Science*, 6, 1926, 167-183; Amos et al., in *East Malling Res. Sta.*, 15th Ann. Rpt., 1923, 43-46; Lee, *Ann. Appl. Biol.*, 9, 1935, 49-65.

*Genus III. Cortum Holmes.*

(Loc. cit., 119.)

Viruses of the Leaf-Roll Group, inducing diseases usually characterized by thickening

*geniculatus*, p.p. of *geniculo*, knotted, jointed.

Medium-sized rods, occurring singly, in pairs and chains, motile, possessing polar flagella. Gram-negative.

Gelatin colonies: Circular, whitish, translucent. Deep colonies yellowish.

Gelatin stab: Infundibuliform liquefaction. Sediment light pink.

Agar slant: Grayish, glistening, translucent, limited, becoming brownish-gray.

Broth: Turbid, with slight gray pellicle and sediment.

Litmus milk: Alkaline; reduction of litmus; slight coagulation.

Potato: Thin, brownish, moist, glistening, viscid.

Indole not formed.

Nitrites not produced from nitrates.

Aerobic, facultative.

Optimum temperature 20° to 25°C.

Habitat: Water.

### 32. *Pseudomonas fragi* (Eichholz)

Huss *emend.* Hussong, Long and Hammer. (*Bacterium fragi* Eichholz, Cent. f. Bakt., II Abt., 9, 1902, 425; Huss, Cent. f. Bakt., II Abt., 19, 1907, 661, Hussong, Long and Hammer, Iowa Agr. Exp. Sta. Res. Bull. 225, 1937, 122; also see Long and Hammer, Jour. Dairy Sci., 20, 1937, 448) From Latin *fragum*, strawberry.

Description from Hussong, Long and Hammer, *loc. cit.*

Rods 0.5 to 1.0 by 0.75 to 4.0 microns, occurring singly, in pairs and in chains. Motile with a polar flagellum. Gram-negative.

Gelatin: Crateriform to stratiform liquefaction in 3 to 4 days.

Agar colonies: Convex, glistening, generally butyrous, occasionally viscid. Rough, smooth and intermediate forms are recognized in the description quoted. The rough forms are less proteolytic, and less active in the hydrolysis of fats.

Agar slant: Growth abundant, spreading, raised, white, shiny, generally butyrous. Sweet ester-like odor resembling that of the flower of the May apple.

Broth: Turbidity and sediment with a thin pellicle.

Litmus milk: Acid ring followed by acid coagulum at surface. Complete coagulation in 2 to 3 weeks, some digestion. Characteristic May apple or strawberry odor.

Potato: Growth echinulate to arborescent, raised, glistening, white, becoming brownish.

Indole not produced.

Nitrites not produced from nitrates.

Ammonia produced from peptone.

Hydrogen sulfide not produced.

Acid from glucose and galactose, sometimes arabinose. No acid from glycerol, inulin, lactose, fructose, maltose, mannitol, raffinose, salicin and sucrose.

No acetylmethylcarbinol produced.

Fat is generally hydrolyzed.

Aerobic.

Grows from 10° to 30°C. No growth at 37°C. Very sensitive to heat.

Source: Isolated from milk and other dairy products, dairy utensils, water, etc.

Habitat: Soil and water. Widely distributed (Morrison and Hammer, Jour. Dairy Sci., 24, 1941, 9).

Hussong (Thesis, Iowa State College, 1932) regards *Bacterium fragi* Eichholz (*loc. cit.*) as the R type, *Pseudomonas fragariae* I Gruber (Cent. f. Bakt., II Abt., 9, 1902, 705) as the O form, and *Pseudomonas fragariae* II Gruber (Cent. f. Bakt., II Abt., 14, 1905, 122) as the S form of the same organism. He makes no mention of *Pseudomonas fragarioidea* Huss (*loc. cit.*) which from its description would belong to the smooth type. A brief characterization of each of these organisms follows: (1) *Bacterium fragi* came from milk as drawn from an individual cow; it does not liquefy gelatin, exhibits no fluorescence, is strongly alkaline in litmus milk, and does not grow at 37°C, (2) *Pseudomonas fragariae* I came from fodder beets; it does not liquefy gelatin, has weak blue-greenish fluorescence, is weakly alkaline in milk, and grows at 37°C, (3) *Pseudomonas fragariae* II came from pasteurized milk; it liquefies gelatin, coagulates milk, and does not grow at 37°C, (4) *Pseudomonas*

*thum solani* Kalt. (APHIDIDAE); virus is not transmitted by these aphids to their descendants. Not through seeds of beet. Virus overwinters in beets stored for subsequent use in seed production.

Serological relationships: Specific precipitating antiserum effective with crude sap of diseased, not healthy, plants and with sap of diseased plants after passage through a Chamberland L<sub>1</sub>, not L<sub>2</sub>, filter candle; ineffective with sap from beet plants suffering from mosaic.

Thermal inactivation: Virus heated to about 52°C no longer precipitates with specific antiserum.

Literature: Kleczkowski and Watson, Ann. Appl. Biol., 31, 1944, 116-120, Petherbridge and Stirrup, London, Ministry Agr. and Fisheries, Bull. 93, 1935, Quanjor and Roland, Tijdschr. Plantenziekten, 42, 1936, 45-70; Roland, *ibid.*, 45, 1939, 1-22, 181-203, Schreven, Meded. Inst. voor Suikerbieteneteelt, Bergen op Zoom, 6, 1936, 1; Watson, Proc. Roy. Soc. London, Ser. B, 128, 1940, 535-552, Ann. Appl. Biol., 29, 1942, 358-365.

3. *Corium rubi* H. (*loc. cit.*, 121). From New Latin *Rubus*, generic name of raspberry, from Latin *rubus*, bramble bush.

Common name: Raspberry leaf-curl virus.

Host: ROSACEAE—*Rubus idaeus* L., red raspberry.

Insusceptible species: ROSACEAE—*Rubus occidentalis* L., black raspberry, *R. neglectus* Peck, purple raspberry.

Geographical distribution: United States, not in England.

Induced disease: In red raspberry, veins retarded in growth, causing downward curling of leaf margins and crinkling of leaf lamina. Foliage dark green, dry in appearance, not wilting readily. In late summer, leaves bronzed, leaf surface glistening. Diseased canes easily winter-killed. Berries small and poor. The

English variety Lloyd George is intolerant of the disease and is killed.

Transmission: By aphid, *Aphis rubicola* Oestl. (= *A. rubiphila* Patch) (APHIDIDAE). Not by inoculation of expressed juice.

Literature: Bennett, Michigan Agr. Exp. Sta., Tech. Bull. 80, 1927; Phytopath., 20, 1930, 787-802, Harris, East Malling Res. Sta., Ann. Rpt. for 1934, 1935, Rankin, New York Agr. Exp. Sta., Geneva, Tech. Bull. 175, 1931.

Strains: A strain differing from the type, var. *alpha* H. (*loc. cit.*, 121), has been given a varietal name derived from its common name, raspberry beta-curl virus.

3a *Corium rubi* var. *beta* H. (*loc. cit.*, 122). Infecting black and purple raspberries, as well as the red raspberry, which alone is susceptible to the type strain, raspberries alpha-curl virus. (Bennett, Phytopath., 20, 1930, 787-802.)

4 *Corium ruborum* (Zeller and Braun) *comb. nov.* (*Minuor ruborum* Zeller and Braun, Phytopath., 33, 1943, 161.) From Latin *rubus*, bramble bush.

Common name: Raspberry decline-disease virus.

Host: ROSACEAE—*Rubus idaeus* L., red raspberry.

Geographical distribution: United States (Oregon).

Induced disease: In Cuthbert raspberry, shoots retarded in spring, reddish; leaves in autumn rolled downward, fluted along veins, less green than normal between veins, slightly bronzed along margins and crests between veins. Internodes shortened near tips of canes. Affected canes small, weak, not hardy in winter. Small roots and feeder rootlets fewer than in healthy plants. Disease progressive over about three years. Fruits small, irregular, tending to be globose, crumbly when ripe, worthless.

Transmission: By grafting. No insect vector is known.

Genus IV. *Nanus* Holmes.

(Loc. cit., 123.)

Viruses of the Dwarf-Disease Group, inducing diseases characterized by dwarfing of host plants or by growth of adventitious shoots with short internodes; chlorotic mottling absent. Generic name from Latin *nanus*, dwarf.

The type species is *Nanus loganobacci* Holmes.

Key to the species of genus *Nanus*.

## I. Infecting rosaceous plants.

## A. In loganberry and Phenomenal berry.

1. *Nanus loganobacci*.

## B. In black raspberry.

2. *Nanus orientalis*.

## C. In peach.

3. *Nanus mirabilis*.

## D. In ocean spray.

4. *Nanus kolodisci*.

## E. In strawberry.

5. *Nanus fragariae*.6. *Nanus cupuliformans*

## F. In prune and plum.

7. *Nanus pruni*.

## II. Infecting graminaceous plants.

## A. In sugar cane.

8. *Nanus sacchari*.

1. *Nanus loganobacci* Holmes.  
(Handb. Phytopath. Viruses, 1939, 124.)

From New Latin *loganobaccus*, specific epithet of loganberry, *Rubus loganobaccus* Bailey.

Common name: Loganberry-dwarf virus.

Hosts. **ROSACEAE**—*Rubus loganobaccus* Bailey, loganberry and Phenomenal berry.

Geographical distribution: United States (Oregon, Washington, and California).

Induced disease In Phenomenal berry, leaves small, obovate, rigid, new canes short, spindly. In young plants, some necrosis along and between veins, leaves crinkled, finer veins chlorotic. Stems not streaked or mottled, normal in color. In late stages, canes very short, internodes short. Sepals and petals of flowers small. Fruit of fair size, but drupelets ripen unevenly and tend to fall apart when picked. Loganberry is less susceptible than the Phenomenal berry but is similarly affected.

Transmission: By aphid, *Capitophorus tetrahodus* (APHIDIDAE). Not by inoculation of expressed juice.

Literature: Zeller, *Phytopath.*, 15, 1925, 732 (Abst.); 17, 1927, 629-648.

2. *Nanus orientalis* H. (loc. cit., 124).  
From Latin *orientalis*, eastern.

Common names: Raspberry-streak virus, raspberry eastern blue-stem virus, raspberry rosette virus.

Host. **ROSACEAE**—*Rubus occidentalis* L., black raspberry.

Insusceptible species: **ROSACEAE**—*Rubus idaeus* L., red raspberry; *R. phoenicolasius* Maxim., Japanese wineberry.

Geographical distribution: United States.

Induced disease: In black raspberry, plants stunted, becoming smaller in successive seasons; leaves usually curled, close together on canes, dark green, often twisted so as to be upside down. New canes show bluish violet dots, spots, or stripes near their bases and sometimes also on branches or on fruiting spurs.

Fruit inferior in size, quality, and quantity. Plants live only 2 or 3 years after infection on the average.

Strains: A strain of this virus is believed responsible for mild streak of black raspberries, in which purple to violet, greenish brown, or bluish streaks on canes are narrowly linear or elliptical in form and often very faint; when the bloom is rubbed off, the lesions appear as though water-soaked and discolored. Leaves are slightly curled, their veins cleared. Fruits are dry and dull in lustre, even while still red, and of poor flavor when ripe.

Literature: Bennett, Michigan Agr. Exp. Sta., Tech. Bull. 80, 1927, Wilcox U. S. Dept. Agr., Dept. Circ. 227, 1923, Woods and Haut, U. S. Dept. Agr., Plant Dis. Rpt., 24, 1910, 338-340.

3. *Nanus mirabilis* H. (*loc. cit.*, 126). From Latin *mirabilis*, strange.

Common name: Peach phony-disease virus.

Hosts: *ROSACEAE*—*Prunus persica* (L.) Batsch, peach. Experimentally, also other *Prunus* species.

Geographical distribution: United States (Georgia, Alabama, Florida; sparsely also in Mississippi, Tennessee, South Carolina, Louisiana, Texas, Arkansas, Missouri).

Induced disease: In peach, tree dwarfed, foliage abnormally green, fruit small, flecks in wood, especially in roots, sections of roots show characteristic well-distributed purple spots after 3 to 5 minutes of treatment in 25 cc absolute methyl alcohol acidulated by the addition of 1 to 5 drops of concentrated, chemically pure hydrochloric acid.

Transmission: By root grafting, except by root-bark patch grafts, which are ineffective. Budding and grafting with parts of stem fail to transmit this virus.

Thermal inactivation: At 45° C in about 40 minutes in roots.

Literature: Hutchins, Georgia State Entomol. Bull., 78, 1933; Phytopath., 22, 1932, 12 (Abst.); Hutchins and Rue, *ibid.*, 22, 1932, 12 (Abst.).

4. *Nanus holodisci* H. (*loc. cit.*, 127). From New Latin *Holodiscus*, generic name of ocean spray.

Common name: Ocean-spray witches'-broom virus.

Host: *ROSACEAE*—*Holodiscus discolor* Max., ocean spray.

Geographical distribution: United States (Oregon and Washington).

Induced disease: In ocean-spray, diseased branches form clusters of thin wiry shoots with abnormally short internodes and crowded small leaves. Laterals numerous and more than normally branched. Bronzy red color acquired early by affected foliage.

Transmission: By aphid, *Aphis spiraeae* Schout. (*APHIDIDAE*). By grafting. Not demonstrated by inoculation of expressed juice.

Literature: Zeller, Phytopath., 21, 1931, 923-925.

5. *Nanus fragariae* H. (Holmes, *loc. cit.*, 128; *Blastogenus fragariae* McKinney, Jour. Washington Acad. Science, 34, 1944, 151.) From New Latin *Fragaria*, generic name of strawberry.

Common name: Strawberry witches'-broom virus.

Host: *ROSACEAE*—*Fragaria chiloensis* Duch. var. *ananassa* Bailey, cultivated strawberry.

Geographical distribution: United States (western Oregon).

Induced disease: In strawberry, leaves numerous, light in color, with spindly petioles, margins of leaflets bent down, runners shortened, plants dwarfed; flower stalks spindly and unfruitful; root systems normal and well developed.

Transmission: By aphid, *Myzus fragariae* Kell. (*APHIDIDAE*). Not demonstrated by inoculation of expressed juice.

Literature: Zeller, Phytopath., 17, 1927, 329-335.

6. *Nanus cupuliformans* Zeller and Weaver. (Phytopath., 31, 1941, 831.) From diminutive of Latin *cupa*, tub, and participial from Latin *formare*, to form.

Common name: Strawberry-stunt virus.

Host: *ROSACEAE*—*Fragaria chiloensis* Duch. var. *ananassa* Bailey, cultivated strawberry.

Geographical distribution: United States (Oregon, Washington).

Induced disease: In strawberry, little if any reduction in chlorophyll, plants erect but short; leaves at first folded, later open, dull in lustre, with papery rattle when brushed by hand, leaflets cupped or with margins turned down, midveins tortuous; petioles  $\frac{1}{2}$  to  $\frac{3}{4}$  normal length; fruits small, usually hard and seedy; roots normal in appearance.

Transmission: By strawberry-leaf aphid, *Capitophorus fragae-folii* (APHIDIDAE). By grafting. Not by inoculation of expressed juice.

7. *Nanus pruni* H. (*loc. cit.*, 128). From New Latin *Prunus*, generic name of prune, from Latin *prunus*, plum tree.

Common name. Prune-dwarf virus.

Hosts: *ROSACEAE*—*Prunus domestica* L., prune and plum; var. *insultitia* Bailey, the Damson plum, remains symptomless. Experimentally, also *Prunus persica* (L.) Batsch, peach.

Insusceptible species: *ROSACEAE*—*Prunus avium* L., cherry.

Geographical distribution: United States (New York); Canada (British Columbia, Ontario).

Induced disease In prune, leaves small, narrow, rugose, distorted, glazed. Internodes short. Some branches escape and appear normal. Blossoms numerous, mature fruits few. Pistils aborted, petals narrow and distorted. In Damson and Bradshaw plums, no obvious manifestations of disease as a result of infection.

Transmission: By budding and other forms of grafting. Not demonstrated by inoculation of expressed juice. No insect vector is known.

Literature: Berkeley, Canada, Domin. Dept. Agr., Div. of Bot. and Plant Path., Science Service, Publ. 679, 1941; Hildebrand, *Phytopath.*, 32, 1942, 741-751; Thomas and Hildebrand, *Phytopath.*, 26, 1936, 1145-1148.

8. *Nanus sacchari* H. (*loc. cit.*, 129). From New Latin *Saccharum*, generic name of sugar cane, from Latin *saccharum*, sugar.

Common name: Sugar-cane sereb-disease virus.

Host: *GRAMINEAE*—*Saccharum officinarum* L., sugar cane.

Geographical distribution: Java, Borneo, Sumatra, Moluccas, India, Mauritius, Australia, Fiji, Formosa, Hawaii, Ceylon.

Induced disease: In sugar cane (Cheribon variety), plant dwarfed, shoots stunted, vascular bundles colored by the presence of a red gum; adventitious roots from many or all nodes.

Transmission: Not by inoculation of expressed juice. No insect vector is known.

Thermal inactivation: In cuttings of sugar cane, at 52° C in 30 minutes to 1 hour. Infected cane cuttings survive the heat treatment required for cure through inactivation of the causative virus.

Literature: Houtman, Arch. Suikerind. Nederland.-Indië, 33, 1925, 631-642; Lyon, Bull. Exp. Sta. Hawaiian Sugar Planters' Assoc., Bot. Ser., 3, 1921, 1-43; Wilbrink, Arch. Suikerind. Nederland.-Indië, 31, 1923, 1-15.

#### Genus V. *Rimocortius* Milbrath and Zeller. (Phytopath., 32, 1942, 430.)

Viruses of the Rough-Bark Group, inducing diseases principally affecting bark, less often wood, leaves, or fruit. Generic name from Latin *rima*, cleft or fissure, and *cortex*, bark.

The type species is *Rimocortius kwanzani* Milbrath and Zeller.

(NOTE: The genus *Citriuir* (first named species, *Citriuir psorosis* Fawcett, Phytopath., 31, 1941, 357) was proposed by its author as a *genus pro tempore* with the avowed purpose of accommodating viruses causing diseases in species of the plant-host genus *Citrus*. It appears to have been implied by the term *genus pro tempore* that evidences of natural relationship, when discovered, would permit even the first-named species of this genus to be assigned elsewhere. On the assumption that a permanent genus is nothing more than a *type species* and such other species as may be added to it by one or another author, it must be felt that a *genus pro tempore*, however convenient as an expedient, cannot become a permanent genus under any circumstances, because its first-named species would appear not to be a permanent part of the genus and so intended not to be a true type-species. Without a type species there would seem to be no permanent genus concept.

The system by which the term *Citriuir* was coined (explained by its author as use of the genitive of the host-genus name, *Citris*, plus *uir*, signifying virus) seems in itself acceptable, for it is commonly agreed that a generic name may be made in an arbitrary manner. It may be noted that use of the stem of the host-genus name (*Citr-*) with connecting vowel *i* and suffix *-uir*, possibly a more orthodox procedure, would have given the same result in the present instance. The original definition of the term *Citriuir* might be thought to be repugnant as disregarding concepts of natural interspecific relationships that are essential to the spirit of binomial nomenclature. Were the genus to be regarded as permanent rather than *pro tempore*, however, the scope of the genus would come to be wholly changed by usage, when, with passage of time related species would be added to what in this case would be a type species, without regard to the unorthodox intent of the original definition but solely in accordance with similarities between viruses. A generic concept need never be accepted as rigidly defined, whether initially, as has been attempted in this case, or upon further experience, because a genus may still grow by the addition of closely allied new species beyond any limit that may be set. On this account an original, or any subsequent, definition may be regarded as subject to unlimited change so long as the type species is logically retained. The form and definition of the term *Citriuir* would not, therefore, militate against its continued use. Its avowedly temporary status alone seems decisively to do so.

The originally monotypic genus *Rimocortius*, published in the following year, was defined only by the combined generic and specific description, and was not referred to a family by its authors. The type, because at first the only species, *Rimocortius kuanzani*, is the flowering-cherry rough-bark virus. This type species might well be associated with the species *Citriuir psorosis*, citrus-psorosis virus, discussed above, both affecting bark principally, though foliage also to some extent. Although the genus *Citriuir* was named in 1941 and *Rimocortius* not until 1942, the first was intended as a temporary assemblage only, as above indicated. It would seem appropriate, therefore, to include the virus that was known temporarily as *Citriuir psorosis* in the permanent genus *Rimocortius* Milbrath and Zeller and to assign this genus to the family *Marmoraceae*.)

*Key to the species of the genus Rimocortius.*

I. Affecting cherry.

1. *Rimocortius kuanzani*.

II. Affecting *Citrus*.

2. *Rimocortius psorosis*.

III. Affecting pear.

3. *Rimocortius pyri*.

1. *Rimocortius kwanzanii* Milbrath and Zeller. (Phytopath., 32, 1942, 430.) From Kwanzan, name of a variety of flowering cherry.

Common name: Flowering-cherry rough-bark virus.

Hosts: *Prunus serrulata* Lindl. var. Kwanzan, flowering cherry; *P. avium* L., Mazzard cherry.

Geographical distribution: United States (Oregon).

Induced disease: In flowering cherry, tree dwarfed, deficient in lateral branches; bark deep brown, roughened, splitting longitudinally; internodes shortened, bunching leaves; leaves arched downward; midribs of leaves split and cracked on under surface. In Mazzard cherry, no manifestation of disease, but carrier condition; budded Mazzard stock may transmit disease to healthy Kwanzan cherry cions.

Transmission: By budding, generally even if the inserted bud fails to survive.

Literature: Milbrath and Zeller, Phytopath., 32, 1942, 428-430; Thomas, *ibid.*, 32, 1942, 435-436.

2. *Rimocortius psorosis* (Fawcett) comb. nov. (*Citriuvr psorosis* Fawcett, Phytopath., 31, 1941, 357) Specific name meaning "of the disease known as psorosis."

Common name: Citrus-psorosis virus.

Hosts: RUTACEAE—*Citrus sinensis* Osbeck, orange; *C. limonia* Osbeck, lemon; *C. maxima* Merr., grapefruit.

Geographical distribution: World-wide where citrus trees are grown.

Induced disease: In citrus, small, elongated, light colored areas or flecks in the region of small veins on young, tender foliage, leaves sometimes warped, (chlorotic?) clearing of veins, and chlorotic line patterns, sometimes concentric. Outer layers of bark scale away, depressions and deformities appear in bark and wood. Lemons, as a rule, are more tolerant than oranges and are not subject to the bark changes.

Transmission: By grafting, including root grafting and patch bark grafting. Not by inoculation of expressed juice. No insect vector is known.

Literature: Bitancourt et al., Phytopath., 33, 1943, 865-883; Fawcett, *ibid.*, 24, 1934, 659-668; Science, 92, 1940, 559-561; Phytopath., 31, 1941, 356-357; Fawcett and Bitancourt, *ibid.*, 33, 1943, 837-864; Rhoads, *ibid.*, 32, 1942, 410-413; Webber and Fawcett, Hilgardia, 9, 1935, 71-109.

Strains: Three strains differing from the type have been recognized. The type, var. *vulgare* Fawcett, Phytopath., 31, 1941, 357, causes psorosis A, the common scaly-bark type of disease, with pustular eruptions of outer layers of bark in limited areas, with or without exudation of gum; later a drab-gray, cinnamon-drab to rufus discoloration of the wood, accompanied by decline of the affected tree. Others, that contrast with the type, are:

2a. *Rimocortius psorosis* var. *annulatum* Fawcett. (Phytopath., 31, 1941, 357.) From Latin *annulatus*, with a ring. Causing psorosis B, known from California, resembling zonate chlorosis of Brazil in effects on leaves and fruits. Psorosis B is characterized by rapid scaling of outer bark in continuous areas, progressing rapidly along one side of trunk or branch; gum exudes in advance of scaling, necrosis follows; large circular discolored and corky spots, sometimes concentric, on fruits and mature leaves; on some fruits, circular or semi-circular furrows and bumps; rapid decline of the affected tree.

2b. *Rimocortius psorosis* var. *concarum* Fawcett and Bitancourt. (Phytopath., 33, 1943, 850.) From Latin *concarus*, concave. Causing concave-gum psorosis, characterized by concavities of various sizes on trunks and larger limbs of affected trees, often by zonate patterns on young leaves during periods of rapid growth.

2c. *Rimocortius psorosis* var. *alveatum* Fawcett and Bitancourt. (Phytopath., 33, 1913, 851.) From Latin *alveatus*, hollowed out like a trough. Causing blind-pocket psorosis, characterized by trough-like pockets in bark and wood or by eruptive lesions.

3. *Rimocortius pyri* (Holmes) comb. nov. (*Marmor pyri* Holmes, Handb. Phytopath. Viruses, 1939, 76) From New Latin *Pyrus*, generic name of pear, from Latin *pirus*, pear tree.

Common name: Pear stony-pit virus.

Host: ROSACEAE—*Pyrus communis* L., pear.

Geographical distribution: United States (Oregon, Washington, California).

Induced disease: In pear, fruit deeply pitted and deformed; bark cracked and resembling oak bark; veinlet chlorosis of some leaves, failure of lateral buds to grow, reduction of foliage. Bartlett and Comice varieties of pear appear to be tolerant, producing sound fruit from infected trees.

Transmission. By budding. Not by inoculation of expressed juice. No insect vector is known.

Literature: Kienholz, Phytopath., 29, 1939, 260-267, 30, 1940, 787 (Abst.).

### Genus VI. *Adelonosus* Brierley and Smith

(Phytopath., 34, 1944, 551.)

Viruses capable of multiplying in living plants but producing no recognizable symptoms in these except on interaction with distinct viruses with which they form complexes. Transmitted by aphids, by sap, or by both means. Generic name from Greek *adēlos*, invisible, and *nosos*, disease. Only one species is recognized thus far; this is the type species, *Adelonosus lilii* Brierley and Smith.

1. *Adelonosus lilii* Brierley and Smith (Phytopath., 34, 1944, 551.) From Latin *lilium*, lily.

Common name: Lily-symptomless virus.

Host: LILIACEAE—*Lilium longiflorum* Thunb., Easter lily.

Insusceptible species: All other tested lilies and many related plants in the same and other families (for list, see Phytopath., 34, 1944, 549).

Geographical distribution. United States, Japan; probably coextensive with commercial culture of Easter lily.

Induced disease: In Easter lily, no obvious manifestation of disease when this virus is present alone; when together with cucumber-mosaic virus, however, the lily-symptomless virus is a determining factor in the production of ne-

crotic-fleck disease; the lily-symptomless virus is so widely distributed in supposedly healthy stocks of the Easter lily that cucumber mosaic virus formerly was thought to be the sole determining factor in necrotic flecking, now recognized to be caused by the virus complex lily-symptomless virus (*Adelonosus lilii*) plus cucumber-mosaic virus (*Marmor cucumeris*), the complex acts independently of the presence or absence of lily latent-mosaic virus (*Marmor lili*), which is often present with the essential members of the complex in flecked Easter lilies.

Transmission. By inoculation of expressed juice, with some difficulty. By aphid, *Aphis gossypii* Glov., cotton aphid (APHIDIDAE); preinfective period after obtaining virus, 4 to 6 days.

## FAMILY III. ANNULACEAE HOLMES.

(Handb. Phytopath. Viruses, 1939, 97.)

Viruses of the Ringspot Group, causing diseases usually characterized by necrotic or chlorotic spotting with concentric-ring lesions and eventual recovery from obvious disease with non-sterile immunity. Hosts, higher plants; vectors unknown. There is a single genus.

Genus I. *Annulus Holmes*.

(Loc. cit., 97.)

Characters those of the family. Generic name from Latin *annulus*, a ring. The type species is *Annulus tabaci* Holmes.

Key to the species of genus *Annulus*.

## I. Found occurring naturally in the Western Hemisphere.

## A. In tobacco.

1. *Annulus tabaci*.
2. *Annulus zonatus*.
3. *Annulus orae*.
4. *Annulus apertus*.

## B. In potato.

5. *Annulus dubius*.

## C. In delphinium.

6. *Annulus delphinii*.

## II. Old World species.

7. *Annulus bergerac*.

1. *Annulus tabaci* Holmes. (Handb. Phytopath. Viruses, 1939, 98, *Marmor anularium* McKinney, Jour. Washington Acad. Sci., 34, 1944, 327.) From New Latin *Tabacum*, early generic name for tobacco

Common names: Tobacco-ringspot virus, green ringspot virus, yellow ringspot virus, ring spot No. 1 virus.

Hosts *SOLANACEAE*—*Nicotiana tabacum* L., *Petunia violacea* Lindl., *Solanum tuberosum* L. *CUCURBITACEAE*—*Cucumis sativus* L. Experimentally this virus has been found capable of infecting many species of plants in a large number of families; these include all tested species of the *SOLANACEAE*, *SCROPHULARIACEAE*, *COMPOSITAE*, and *CUCURBITACEAE*. Many species of the *LEGUMINOSAE* are susceptible and one, *Vigna sinensis* (L.) Endl., is used as an indicator plant for quantitative measurement because it displays conspicuous reddish-brown necrotic lesions around points of initial infection.

Geographical distribution: United States.

Induced disease: In tobacco, necrotic ring-like primary lesions, followed by secondary necrotic rings on younger leaves. Subsequently, affected plants recover. After recovery from obvious disease, virus content of plants is only 10 to 20 per cent of that of recently infected plants. Some varieties may show mosaic-like patterns in young leaves at 16°C.

Transmission: By inoculation of expressed juices. Through about 20 per cent of seeds from diseased petunia plants. Not by dodder, *Cuscuta campestris* Yuncker (*CONVOLVULACEAE*).

Serological relationships: Induces the formation of specific precipitating antibodies when injected into bloodstream of rabbit.

Immunological relationships: Recovered tobacco plants are not susceptible to reinfection with this virus but are readily infected with *Annulus zonatus* or *A. orae*. This virus produces primary lesions on

leaves of plants immune to reinfection with *A. bergerae*.

Thermal inactivation: At 68° C in 10 minutes.

Filterability: Passes V, N, and perhaps W Berkefeld filters.

Other properties: Particle size estimated by filtration experiments as about 19 millimicrons. Sedimentation constant,  $S_{20}^w = 115 \times 10^{-11}$  cm. sec.<sup>-1</sup> dyne<sup>-1</sup>. Infective in dilutions of  $10^{-7}$  after purification. Inactivated in 1 hour below pH 3 or above pH 10.8. Recovered plants of tobacco contain 0.002 mg of virus per gram, recently infected plants about 6 times as much. Optimum conditions for retaining infectivity of stored virus include suspension in 0.01 M phosphate buffer at pH 7 and storage at 4° C.

Literature: Fenne, *Phytopath.*, 21, 1931, 891-899; Fromme et al., *ibid.*, 17, 1927, 321-328; Henderson, *ibid.*, 21, 1931, 225-229; Henderson and Wingard, *Jour. Agr. Res.*, 45, 1931, 191-207; Price, *Contrib. Boyce Thompson Inst.*, 4, 1932, 359-403; *Phytopath.*, 26, 1936, 503-529; *Am. Jour. Bot.*, 27, 1940, 530-541; *Am. Naturalist*, 74, 1940, 117-128; Priode, *Am. Jour. Bot.*, 16, 1928, 88-93; Stanley, *Jour. Biol. Chem.*, 129, 1939, 405-428, 429-436; Stanley and Wyckoff, *Science*, 85, 1937, 181-183; Valteau, *Kentucky Agr. Exp. Sta. Bull.*, 327, 1932; Wingard, *Jour. Agr. Res.*, 37, 1928, 127-153; Woods, *Contrib. Boyce Thompson Inst.*, 6, 1933, 419-431.

Strains A number of distinctive strains have been collected in nature and studied experimentally. The following have been given varietal names to distinguish them from the type, var. *virginicus* H., *loc. cit.*, 98:

1a. *Annulus tabaci* var. *kentuckiensis* H. (*loc. cit.*, 99). Differing from the typical strain in producing less necrosis and less stunting in tobacco. (Price, *Phytopath.*, 26, 1936, 665-675; Valteau, *Kentucky Agr. Exp. Sta. Bull.*, 327, 1932.)

1b. *Annulus tabaci* var. *auratus* H. (*loc. cit.*, 100). Secondary lesions in

tobacco at first yellow spots or rings, becoming necrotic subsequently. Recovery less complete than with type, abnormal yellowing of old leaves tending to persist. (Chester, *Phytopath.*, 25, 1935, 686-701; Price, *Phytopath.*, 26, 1936, 665-675; Valteau, *Kentucky Agr. Exp. Sta. Bull.*, 327, 1932, *Phytopath.*, 29, 1939, 549-551.)

2. *Annulus zonatus* H. (*loc. cit.*, 101). From Latin *zonatus*, zonate.

Common names: Tomato-ringspot virus, ring spot No. 2 virus.

Hosts: *SOLANACEAE*—*Nicotiana tabacum* L., tobacco. Experimentally this virus has been found to infect many species of plants in a large number of families.

Geographical distribution: United States.

Induced disease. In tobacco, zonate necrotic primary lesions and, temporarily, secondary lesions of the same type; recovery with specific, non-sterile immunity. In tomato, systemic infection, yellowish-green or necrotic ring-like lesions, stunting.

Transmission. By inoculation of expressed juice.

Immunological relationships: Recovered plants are immune to reinfection but are still susceptible to *Annulus tabaci*, *A. bergerae*, and several mosaic-type viruses that have been tested.

Thermal inactivation. At 55 to 60° C in 10 minutes.

Filterability: Passes Gradocol membrane 100 millimicrons in average pore diameter. Particle size estimated as 50 millimicrons or less.

Literature: Price, *Phytopath.*, 26, 1936, 665-675; *Am. Jour. Bot.*, 27, 1940, 530-541.

3. *Annulus orae* H. (Holmes, *loc. cit.*, 103, *Tractus orae* Valteau, *Phytopath.*, 30, 1940, 825). From Latin *ora*, edge, in reference to occurrence of induced disease near edge of tobacco fields.

Common name: Tobacco-streak virus.

Hosts: *SOLANACEAE*—*Nicotiana tabacum* L., tobacco. Experimentally, a

number of other solanaceous plants have been reported as susceptible, but not *Capsicum frutescens* L., pepper; *Lycopersicon esculentum* Mill., tomato; *Solanum melongena* L., eggplant; or *S. tuberosum* L., potato.

Geographical distribution: United States.

Induced disease: In tobacco, local and systemic necrosis in 3 days, with irregular spot, line, and ring-like lesions, followed by recovery from necrotic manifestations of disease. Recovered leaves may show a mild mottling and regularly contain virus; reinoculation does not induce formation of necrotic lesions in them.

Transmission: By inoculation of expressed juice. Not through seeds from diseased plants.

Immunological relationships: No cross-protection with respect to *A. tabaci*, and several viruses of the mosaic group.

Thermal inactivation: At 53° C in 10 minutes.

Literature: Johnson, Phytopath., 26, 1936, 285-292; Trans. Wisconsin Acad. Sciences, Arts and Letters, 50, 1937, 27-34.

4. *Annulus apertus spec. nov.* From Latin *apertus*, frank.

Common name: Broad-ringspot virus.

Hosts: **SOLANACEAE**—*Nicotiana tabacum* L., tobacco. Experimentally also to many species in this and other families.

Insusceptible species: **CHENOPODIACEAE**—*Beta vulgaris* L. **CUCURBITACEAE**—*Citrullus vulgaris* Schrad. **LEGUMINOSAE**—*Medicago sativa* L., *Melilotus alba* Desr.

Geographical distribution: United States (Wisconsin).

Induced disease: In tobacco, indistinct yellow-spot primary lesions, becoming chlorotic or necrotic rings with concentric markings; small chlorotic rings, sometimes concentric, or fine brown necrotic rings as secondary lesions; young leaves puckered at first, somewhat malformed.

Transmission: By inoculation of expressed juice.

Immunological relationships: Protects against reinfection with homologous virus but leaves host susceptible to infection by *Annulus tabaci*, *A. zonatus*, and some mosaic-type viruses.

Literature: Johnson and Fulton, Phytopath., 32, 1942, 605-612.

5. *Annulus dubius* (Holmes) *comb. nov.* (*Marmor dubium* H., *loc. cit.*, 42.) From Latin *dubius*, uncertain, in reference to a common name, potato virus X, often used to designate this virus.

Common name: Potato-mottle virus (strains of this virus have been studied at various times under the names potato latent virus, potato virus X, potato-necrosis virus, virulent latent virus, simple mosaic virus, healthy potato virus, *Hyoscyamus* IV virus, President streak virus, potato foliar-necrosis virus, potato acronecrotic streak virus, Up-to-Date streak virus, potato viruses B and D, *Solanum* viruses 1, 4, and 6.)

Hosts: **SOLANACEAE**—*Solanum tuberosum* L., potato; *Lycopersicon esculentum* Mill., tomato. Experimentally, also **SOLANACEAE**—*Capsicum frutescens* L., pepper; *Datura stramonium* L., Jimson weed; *Hyoscyamus niger* L., henbane; *Nicotiana tabacum* L., tobacco; *Physalis alkekengi* L.; *Solanum dulcamara* L., bitter-sweet; *S. nigrum* L., black nightshade. **AMARANTHACEAE**—*Amaranthus retroflexus* L. **COMPOSITAE**—*Chrysanthemum morifolium* Ram. **SCROPHULARIACEAE**—*Veronica* sp., common speedwell.

Geographical distribution: Widespread throughout the world; present in all known stocks of tubers of some potato varieties in the United States.

Induced disease: In potato, usually no chlorotic mottling, sometimes a little; intracellular inclusions of the vacuolated, granular type; some varieties that are virtually immune in the field owe their tendency to localize the virus in necrotic primary lesions or in top-necrosis of first systemically infected plants to a dom-

*fragaroidea* came from butter; it liquefies gelatin, coagulates milk, and grows at 37°C.

\*33. *Pseudomonas nebulosa* (Wright) Chester. (*Bacillus nebulosus* Wright, Memoirs Nat. Acad. Sci., 7, 1895, 465; Chester, Man. Determ. Bact., 1901, 311; *Achromobacter nebulosum* Bergey et al., Manual, 1st ed., 1923, 145; not *Bacillus nebulosus* Hallé, Thèse de Paris, 1898; not *Bacillus nebulosus* Vincent, Ann. Inst. Past., 21, 1907, 69; not *Bacillus nebulosus* Migula, Syst. d. Bakt., 2, 1900, 844; not *Bacillus nebulosus* Goresline, Jour. Bact., 27, 1934, 52.) From Latin, *nebula*, mist.

Medium-sized rods, occurring singly Motile, possessing polar flagella. Gram-negative.

Gelatin colonies: Thin, circular, gray, translucent, hazy, with white center

Gelatin stab: Crateriform liquefaction

Agar slant: Thin, transparent streak.

Broth: Turbid, with gray sediment.

Litmus milk: Alkaline; reduction of litmus.

Potato: Scanty growth.

Indole not formed.

Nitrites not produced from nitrates.

Sugar gelatin in deep stab. Fair growth, with some gas formation.

Aerobic, facultative.

Optimum temperature 30° to 35°C

Habitat: Water.

Probable synonym: *Pseudomonas centrifugans* Chester. (Man. Determ. Bact., 1901, 312; *Bacillus centrifugans* Wright, Mem. Nat. Acad. Sci., 7, 1895, 462.)

34. *Pseudomonas coadunata* (Wright) Chester. (*Bacillus coadunatus* Wright, Memoirs Nat. Acad. Sci., 7, 1895, 460; Chester, Man. Determ. Bact., 1901, 310; *Achromobacter coadunatum* Bergey et al., Manual, 1923, 147.) 1st ed., From Latin, *coadunatus*, to unite closely.

Medium-sized rods, with rounded ends, occurring singly, in pairs and in chains. Motile, possessing a polar flagellum. Gram-negative.

Gelatin colonies: Circular, brownish, dense.

Gelatin stab: Crateriform to stratiform liquefaction.

Agar slant: Gray, translucent, spreading.

Broth: Turbid, with gray pellicle and sediment. The medium has a slight greenish tint.

Litmus milk: Acid; coagulated.

Indole is formed.

Nitrites not produced from nitrates.

Sugar gelatin in deep stab: Good growth

of discreet and confluent whitish colonies.

Marked gas production; no liquefaction.

Aerobic, facultative.

Optimum temperature 20° to 25°C.

Habitat: Water.

35 *Pseudomonas multistriata* (Wright) Chester. (*Bacillus multistriatus* Wright, Memoirs Nat. Acad. Sci., 7, 1895, 462; Chester, Man. Determ. Bact., 1901, 310; *Achromobacter multistriatum* Bergey et al., Manual, 1st ed., 1923, 147) From Latin, *multus*, many, much; *striatus*, grooved.

Medium-sized rods, with rounded ends, occurring singly and in pairs. Motile, possessing polar flagella. Gram-negative.

Gelatin colonies: Circular, grayish-white, translucent.

Gelatin stab: Crateriform liquefaction.

Agar slant: Narrow, translucent, grayish streak.

Broth: Turbid.

Litmus milk: Slightly acid; coagulated.

Potato. Grayish to creamy, thick, glistening, viscid, spreading.

Indole not formed.

Nitrites not produced from nitrates.

Sugar gelatin in deep stab: Vigorous growth with marked gas production; also liquefaction.

\*Prof. E. R. Hitchner, Univ. of Maine, Orono, Maine assisted in rearranging the descriptions of the acid and gas producing pseudomonads (*Aeromonas*), April, 1913

anisotropy of flow. Destroyed by drying. Inactivated by papaine and cyanide, but by neither separately. Digested by 0.02 per cent solution of pepsin in 3 hours at pH 4, at 38° C. Digested also by trypsin. About 6 per cent of the purified virus is reported to be a pentose nucleic acid, but the carbohydrate to phosphorus ratio is about twice that for yeast nucleic acid. Guanine and pentose present. Analysis of sedimented virus, carbon 47.7 to 49.5 per cent, hydrogen 6.8 to 7.7 per cent, nitrogen 14.6 to 17.0 per cent, phosphorus 0.4 to 0.7 per cent, sulfur 1.1 per cent, carbohydrate 2.5 to 4.3 per cent, ash 2.0 to 2.5 per cent. Reduction of carbohydrate content of sample to 2.5 per cent does not reduce activity of virus; further reduction inactivates. (Ainsworth, *Ann. Appl. Biol.*, **21**, 1934, 581-587; Bawden, *Brit. Jour. Exp. Path.*, **16**, 1935, 435-443; Bawden and Pirie, *ibid.*, **19**, 1938, 66-82; Birkeland, *Bot. Gaz.*, **26**, 1934, 419-436; Chester, *Phytopath.*, **26**, 1936, 778-785; Johnson, *Wisconsin Agr. Exp. Sta., Res. Bull.* **76**, 1927; Loring, *Jour. Biol. Chem.*, **126**, 1938, 455-478; Loring and Wyckoff, *ibid.*, **121**, 1937, 225-230.)

5b. *Annulus dubius* var. *flavus* H. (*loc. cit.*, 46). From Latin *flavus*, yellow.

Common name: Yellow-mottle strain of potato-mottle virus. Differing from the type by imparting a yellow cast to foliage of infected potatoes. (Putnam, *Canad. Jour. Res., Sec. C*, **15**, 1937, 87-107.)

5c. *Annulus dubius* var. *obscurus* H. (*loc. cit.*, 46). From Latin *obscurus*, obscure. Common name. Masked-mottle strain of potato-mottle virus. Differing from the type by systemically infecting potato, tobacco, and Jimson weed without symptoms under ordinary experimental conditions; in pepper, however, systemic necrosis is induced, as by all known strains. (Chester, *Phytopath.*, **26**, 1936, 778-785.)

6. *Annulus delphinii spec. nov.* From New Latin *Delphinium*, generic name of host.

Common names: Delphinium-ringspot virus, perennial-delphinium ringspot virus.

Hosts: **RANUNCULACEAE**—*Delphinium* sp., perennial delphinium. Experimentally, also to **CHENOPODIACEAE**—*Beta vulgaris* L. **CUCURBITACEAE**—*Cucumis sativus* L., cucumber. **MALVACEAE**—*Gossypium hirsutum* L. **RANUNCULACEAE**—*Ranunculus asiaticus* L. (symptomless carrier). **SOLANACEAE**—*Datura stramonium* L., *Nicotiana glauca* Link and Otto, *N. glutinosa* L., *N. rustica* L., *N. tabacum* L., *Petunia hybrida* Vilm.

Geographical distribution: United States (California).

Induced disease: In perennial delphiniums, faint chlorotic rings with green or yellow centers on young leaves, irregular chlorotic spots, yellow bands, or irregular chlorotic rings on mature leaves.

Transmission: By inoculation of expressed juice in the presence of finely powdered carborundum.

Thermal inactivation: At 65° C in 10 minutes.

Literature: Severin and Dickson, *Hilgardia*, **14**, 1942, 465-490.

7. *Annulus bergerac* H. (*loc. cit.*, 102). From Bergerac, a town in southwest France.

Common name. Bergerac-ringspot virus.

Hosts: **SOLANACEAE**—*Nicotiana tabacum* L., tobacco. Experimentally, this virus has been transferred to several other solanaceous plants and to *Phaseolus vulgaris* L., bean, in the family **LEGUMINOSAE**.

Geographical distribution: France.

Induced disease: In tobacco, thin necrotic-ring primary lesions, followed by

inant allele of a gene *nr*, which characterizes plants showing a mosaic of some degree of intensity on infection with this virus; the variety known as S41956 is immune to all tested strains of the virus and possesses two dominant genes both required for resistance. In tomato, systemic mild chlorotic mottling; if a strain of tobacco-mosaic virus is also present, a severe systemic necrosis, known as double-virus streak, is induced.

**Transmission:** By inoculation of expressed juice. Experimentally, by leaf contacts mainly under the influence of wind. No insect vector is known. Not transmitted through true seeds of the potato.

**Serological relationships:** Cross precipitation reactions between constituent strains of this virus. No cross reaction with potato aucuba-mosaic, potato mild-mosaic, potato-veinbanding, tobacco-mosaic, tobacco-etch, tobacco-ringspot or pea mosaic virus. Antisera prepared by injecting rabbits intravenously with virus inactivated by nitrous acid, like those prepared with active virus, fix complement and flocculate with virus suspensions (though not with juice of healthy host plants), they are also effective in neutralizing the virus.

**Immunological relationships:** Tobacco and *Datura* plants infected by the type strain of this virus become immune to the more severe potato-ringspot strain. No protection against the severe strain is afforded by previous infection with tobacco-mosaic, tobacco-ringspot, tomato spotted-wilt, or cucumber-mosaic virus.

**Thermal inactivation:** At 70° C in 10 minutes

**Filterability:** Passes Pasteur-Chamberland L<sub>1</sub>, L<sub>2</sub>, and L<sub>3</sub> filters.

**Other properties:** Digested by 0.02 per cent solution of pepsin in 3 hours at pH 4, at 35° C. Digested also by trypsin. Inactivated by papaine and cyanide, but by neither separately. Isoelectric point near pH 4. Dilute solutions show anisotropy of flow. Concentrated solutions are spontaneously birefringent. Properties of the type strain have been less

studied than those of the potato-ringspot strain of this virus.

**Literature:** Bawden, Proc. Roy. Soc. London, Ser. B, 116, 1934, 375-395; Bawden and Pirie, Brit. Jour. Exp. Path., 17, 1936, 64-74; Bawden et al., *ibid.*, 17, 1936, 201-207; Blodgett, Phytopath., 17, 1927, 775-782; Böhme, Phytopath. Ztschr., 6, 1933, 517-524; Cadman, Jour. **Strains:** Several variants of potato-mottle virus, differing from the type, var. *vulgaris* II. (*loc. cit.*, 42), have been recognized as distinctive varieties under the following names:

5a. *Annulus dubius* var. *annulus* II. (*loc. cit.*, 44). From Latin *annulus*, ring.

**Common name:** Ringspot strain of potato-mottle virus. Necrotic primary and secondary ring-like lesions in experimentally infected tobacco plants. Indistinguishable from type strain by ordinary precipitation test, but distinguishable when appropriately absorbed sera are used. This strain has been more frequently studied than the type. Juice of infected tobacco plants contains about 0.02 to 0.10 mg of virus per ml. Sedimentation constants,  $S_{20}^w = 113 \times 10^{-13}$  and  $131 \times 10^{-13}$  cm. sec.<sup>-1</sup> dyne<sup>-1</sup>. Dissymmetry constant 2.78. Molecular weight  $26 \times 10^6$ . Particle size estimated to be 433 by 9.5 millimicrons, 43.9 times as long as wide. Isoelectric point near pH 4. Stable between pH 4 and pH 9.5. Concentrated solutions are spontaneously birefringent. Dilute solutions show

## FAMILY IV. RUGACEAE HOLMES.

(Handb. Phytopath. Viruses, 1939, 114)

Viruses of the Leaf-Curl Group, causing diseases characterized by suddenly arrested development of invaded tissues, resulting in leaf curl, enations, and other deformities. Vectors, typically white-flies (*ALEYRODIDAE*). There is a single genus.

Genus I. *Ruga* Holmes.

(Loc. cit., 114.)

Characters those of the family. Generic name from Latin *ruga*, a wrinkle. The type species is *Ruga tabaci* Holmes.

Key to the species of genus *Ruga*.

## I. Infecting tobacco.

1. *Ruga tabaci*.

## II. Infecting cotton.

2. *Ruga gossypii*.III. Infecting cassava (*Manihot*).3. *Ruga bemisiae*.

## IV. Infecting sugar-beet.

4. *Ruga verrucosana*.

1. *Ruga tabaci* Holmes. (Handb. Phytopath. Viruses, 1939, 115.) From New Latin *Tabacum*, former generic name of tobacco.

Common names: Tobacco leaf-curl virus, kroepoek virus, curl-disease virus, crinkle-disease virus.

Hosts: *SOLANACEAE*—*Nicotiana glauca* L., tobacco. *COMPOSITAE*—*Vernonia tomentosa* L., *V. cinerea*, *Ageratum conyzoides* L., *Synedrella nodiflora* Gaertn. Experimentally, also other solanaceous plants.

Insusceptible species: *MALVACEAE*—*Gossypium hirsutum* L., cotton.

Geographical distribution: Tanganyika, Southern Rhodesia, Southern Nigeria, Nyasaland, India, Sumatra, Formosa.

Induced disease: In tobacco, leaves curled and crinkled, with occasional leafy outgrowths or enations. Veins greened and thickened. No chlorosis nor necrosis. Plant stunted.

Transmission. By white-fly, *Bemisia gossypiperda* Misra and Lamba (*ALEYRODIDAE*). By grafting. Not by inoculation of expressed juice.

Literature: Kerling, Phytopath., 25, 1933, 175-190; Mathur, Indian Jour. Agr.

Sci., 3, 1933, 80-96; Matsumoto and Tateoko, Trans. Nat. Hist. Soc. Formosa, 30, 1940, 31-33; Pal and Tandon, Indian Jour. Agr. Sci., 7, 1937, 363-393; Pruthi and Samuel, *ibid.*, 7, 1937, 659-670; Storey, Nature, 128, 1931, 187-188; East African Agr. Jour., 1, 1935, 148-153; Thung, Meded. Proefsta. Vorstenl. Tabak Java, 72, 1932; 78, 1934.

2. *Ruga gossypii* H. (loc. cit., 116). From Latin *gossypium*, cotton.

Common names: Cotton leaf-curl virus, cotton leaf-crinkle virus.

Hosts: *MALVACEAE*—*Gossypium*

*Althaea rosea* Cav., hollyhock; *Sakel* (hybrid) cotton.

Geographical distribution: The Sudan and Nigeria, in Africa.

Induced disease: In cotton, clearing of veins, blistering and pale spotting of leaves; leaves puckered at edge and unsymmetrical. Internodes shortened, producing bunched growth.

Transmission: By white-fly, *Bemisia gossypiperda* Misra and Lamba (*ALEY-*

systemic mottling with some chlorotic rings on the dark green islands. Later, complete recovery occurs, with non-sterile immunity.

Transmission: By inoculation of expressed juice.

Immunological relationships: Recov-

ered plants are susceptible to infection by *Annulus tabaci* and *A. zonatus*.

Thermal inactivation: At 80° C in 10 minutes.

Literature: Smith, A textbook of plant virus diseases, P. Blakiston's Son and Co., Inc., Philadelphia, 1937, 285-289.

the end of the season, showing puckering and downward curling of leaves at the top of the plant, reduction in size of new leaves, and shortened internodes, or they may gradually become chlorotic and die.

**Transmission:** By leafhopper, *Eutettix tenellus* (Baker) (CICADELLIDAE) with 4 to 12 hour preinfective period. Through dodder, *Cuscuta campestris* Yuncker (CONVOLVULACEAE). Not, with any regularity at least, by mechanical inoculation of expressed juice. Not through seeds of diseased plants to seedlings germinating from them. The leafhopper, *Agalliana ensigera* Oman (CICADELLIDAE), is said to transmit a South American strain of sugar-beet curly-top virus, but evidence for identity of the virus has not yet been reported in detail.

**Thermal inactivation:** At 75° to 80° C in 10 minutes.

**Filterability:** Passes Berkefeld V, N, and W, Mandler medium and fine, and Chamberland L<sub>1</sub>, L<sub>3</sub>, L<sub>5</sub>, L<sub>7</sub>, L<sub>8</sub>, L<sub>11</sub> and L<sub>15</sub> filters.

**Other properties:** Withstands alcohol and acetone treatments. A pH of 2.0 or lower inactivates, but an alkaline reaction as high as pH 9.1 does not inactivate, in 2 hours. Virus active after at least 8 years in tissues of thoroughly dried young

sugar-beet plants, 6 months in dried leafhoppers, and 10 months in dried phloem exudate.

**Strains:** In general it has proved possible to modify strains by host passage, some hosts like *Chenopodium murale* L. appearing to select less virulent strains, others like *Stellaria media* (L.) Cyr. reversing this selection and restoring virulence.

**Literature:** Bennett, Jour. Agr. Res., 48, 1934, 665-701; 50, 1935, 211-241; 56, 1938, 31-52; Phytopath., 32, 1942, 826-827; Carsner, Phytopath., 15, 1925, 745-757; U. S. Dept. Agr., Tech. Bull. 360, 1933; Jour. Agr. Res., 33, 1926, 345-348; Dana, Phytopath., 28, 1938, 649-656; Fawcett, Revista Industrial y Agrícola de Tucumán, 16, 1925, 39-46; Fife, Phytopath., 30, 1940, 433-437; Giddings, Phytopath., 27, 1937, 773-779; Jour. Agr. Res., 56, 1938, 883-891; Lackey, Jour. Agr. Res., 55, 1937, 453-460; Lesley and Wallace, Phytopath., 28, 1938, 543-553; Murphy, *ibid.*, 30, 1940, 779-784; Severin, Hilgardia, 3, 1929, 595-636; Severin and Freitag, *ibid.*, 8, 1933, 1-48; Severin and Henderson, Hilgardia, 3, 1928, 339-393; Severin and Swezy, Phytopath., 18, 1928, 681-690; Shaw, U. S. Dept. Agr., Bull. 181, 1910.

**RODIDAE**). Not through egg of insect vector. Not by inoculation of expressed juice. Not through soil. Not through seeds from diseased plants.

Literature: Bailey, Empire Cotton Growing Rev., 11, 1934, 280; Kirkpatrick, Bull. Entom. Res., 21, 1930, 127-137; 22, 1931, 323-363.

3. *Ruga bemisiae* H. (Holmes, loc. cit., 117; *Ochrosticta bemisiae* McKinney, Jour. Washington Acad. Sci., 34, 1944, 149.) From New Latin *Bemisia*, generic name of insect vector.

Common names: Cassava-mosaic virus, cassava Kräuselkrankheit virus.

Hosts: **EUPHORBIACEAE**—*Manihot utilisissima* Pohl, cassava; *M. palmata* Muell., *M. dulcis*.

Geographical distribution: Gold Coast, Belgian Congo, French Cameroons, Rhodesia, Liberia, Madagascar, probably throughout Africa and adjacent islands; Java.

Induced disease: In *Manihot utilisissima*, leaves unsymmetrical, curled, distorted, mottled, internodes shortened, plants stunted. Axillary buds produce an extra number of side branches.

Transmission. By white-flies (**ALEYRODIDAE**), *Bemisia nigricornis* Corb., in Southern Nigeria, and *B. gossypiperda* Misra and Lamba, in Belgian Congo and Tanganyika. White-flies infect only young leaves. Not by needle-puncture, rubbing, or hypodermic-needle injection of juice expressed from diseased plants.

Literature Dade, Yearbk. Dept. Agr. Gold Coast, 1930, 215; Dufrenoy and Hedén, Rev. Bot. Appl., 3, 1929, 361-365; Golding, Trop. Agric., Trinidad, 13, 1936, 182-186; Kufferath and Ghesquière, Compt. rend. Soc. Biol. Belge, 109, 1932, 1146; Lefevre, Bull. Agr. Congo Belge, 26, 1935, 442; McKinney, Jour. Agr. Res., 33, 1929, 557-578; Muller, Bull. Inst. Plantenziekt., 24, 1931, 1-17; Pascalet, Agron. Colon, 21, 1932, 117; Staner, Bull. Agr. Congo Belge, 22, 1931, 75; Storey, East Afr. Jour., 2, 1936, 34-39; Storey and Nichols, Ann. Appl. Biol., 25, 1938, 790-806; Zimmermann, Pflanzer, 2, 1906, 145.

4. *Ruga verrucosans* Carsner and Bennett. (*Chlorogenus eutetticola* (in error for *eutettigicola*, from New Latin *Eutettiz*, genus name of a vector, and Latin *-cola*, dweller in or inhabitant of) Holmes, 1939, loc. cit., 11; Carsner and Bennett, Science 98, 1943, 386.) From Latin, meaning: causing rough swellings.

Common name: Sugar-beet curly-top virus.

Hosts. Very wide range in many families of dicotyledonous plants. Among the horticulturally important host plants are the sugar beet (*Beta vulgaris* L., **CHENOPODIACEAE**); bean (*Phaseolus vulgaris* L., **LEGUMINOSAE**); squash (*Cucurbita* species, **CUCURBITACEAE**); and tomato (*Lycopersicon esculentum* Mill., **SOLANACEAE**).

Geographical distribution: Western North America; in Argentina a strain of virus thought to belong here has been reported but has not yet been fully described.

Induced disease: In beet, clearing of veins, leaf curling, sharp protuberances from veins on lower surface of leaves, increase in number of rootlets, phloem degeneration followed by formation of supernumerary sieve tubes, retardation of growth. In tomato, (western yellow blight or tomato yellows), phloem degeneration followed by formation of supernumerary sieve tubes, retardation of growth, dropping of flowers and buds, rolling, yellowing and thickening of leaves, root decay, usually followed by death, sometimes by recovery. Occasionally there is relapse after recovery. In cucurbitaceous plants, stunting, bending upward of tip of runner, yellowing of old leaves, abnormally deep green in tip leaves and stem; Marblehead squash is tolerant, showing only mild witches' broom formation and phyllody. In bean, infected when young, thickening and downward curling of first trifoliate leaf, which becomes brittle and will break easily from the stem; leaves become chlorotic plant stunted.

Transmission: By inoculation of expressed juice. By the tarnished plant bug, *Lygus pratensis* Linn. (*MIRIDAE*). The insect vector retains this virus during intervals between crops.

Literature: Kaufmann, Arb. Biol. Reichsanst. Land- u. Forstw., *21*, 1936, 605-623; Mitteil. Landwirtsch., *37*, 1936; Pape, Deutsch. Landwirtsch. Presse, *26*, 1935.

## FAMILY V. SAVOIACEAE HOLMES

(Handb. Phytopath. Viruses, 1939, 131.)

Viruses of the Savoy-Disease Group, causing diseases characterized mainly by crinkling of foliage. Vectors, true bugs (*PIESMIDAE* and *MIRIDAE*). There is a single genus.

*Genus I. Savoia Holmes.*

(Loc. cit., 131.)

Characters those of the family. Generic name from French *chou de Savoie*, cabbage of Savoy, a cabbage with wrinkled and curled leaves.

The type species is *Savoia betae* Holmes.

*Key to the species of genus Savoia.*

## I Infecting beet.

1. *Savoia betae*.2. *Savoia piesmae*.

## II. Infecting rape and rutabaga.

3. *Savoia napi*.

1 *Savoia betae* Holmes. (Handb. Phytopath. Viruses, 1939, 132.) From Latin *beta*, beet.

Common names: Beet-Kräuselkrankheit virus, sugar-beet leaf-curl virus, sugar-beet leaf-crinkle virus, Kopfsalat virus.

Host *CHENOPODIACEAE*—*Beta vulgaris* L., beet.

Geographical distribution: Germany, Poland

Induced disease: In beet, veins of leaves swollen, retarded in growth, causing crinkling. New leaves remain small and incurved, forming a compact head. Old leaves die, plant succumbs before harvest time. Prepatent period in plant, 3 to 9 weeks

Transmission: By tingid bug, *Piesma quadrata* Fieb. (*PIESMIDAE*). Not by inoculation of expressed juice.

Literature: Willé, Arb. Biol. Reichsanst. Land- u. Forstw., 16, 1928, 115-167.

2. *Savoia piesmae* H. (loc. cit., 132)

From New Latin *Piesma*, generic name of insect vector.

Common name: Beet savoy virus.

Host *CHENOPODIACEAE*—*Beta vulgaris* L., beet

Geographical distribution: United States (Michigan, Ohio, Minnesota, Nebraska, South Dakota, Colorado, Wyoming) and Canada.

Induced disease: In beet, leaves dwarfed, curled down, small veins thickened. Phloem necrosis in roots. Prodromal period in plant, 3 to 4 weeks.

Transmission: By tingid bug, *Piesma cinerea* (*PIESMIDAE*). Not by inoculation of expressed juice.

Literature: Coons et al., Phytopath., 27, 1937, 125 (Abst.); Hildebrand and Koch, *ibid.*, 32, 1942, 328-331.

3. *Savoia napi* H. (loc. cit., 133). From New Latin *Napus*, former generic name of rape, *Brassica napus* L.

Common name: Rape-savoy virus.

Hosts: *CRUCIFERAE*—*Brassica napus* L., rape, *B. napobrassica* Mill., rutabaga

Geographical distribution: Germany.

Induced disease: In rape, twisting and crinkling of young leaves; premature death of old leaves and of plants; in surviving plants, inhibition of growth in spring. In rutabaga, mottling and crinkling of leaves, with formation of fissures at leaf edges. Plants rarely killed.

infective thrips. Probably not through seeds of infected plants. Not through soil.

Immunological relationships: Infects tobacco plants previously infected with tobacco-mosaic, potato-mottle, tobacco-ringspot, and tomato-ringspot viruses.

Thermal inactivation: At 42° C in 10 minutes.

Filterability: Passes Gradocol membrane of 0.45 micron pore diameter.

Other properties: Virus readily inactivated by desiccation or by action of oxidizing agents; activity prolonged by presence of sodium sulfite, cysteine, or by low temperatures. Unstable at pH values below 6 and above 9.

Literature. Ainsworth et al., Ann. Appl. Biol., 21, 1934, 566-580; Andrewartha, Trans. Roy. Soc. of So. Australia, 61, 1937, 163-165; Bald and Samuel, *ibid.*, 21, 1934, 179-190; Berkeley, Scientific Agr., 15, 1935, 387-392; Best, Austral. Chem. Inst. Jour. and Proc., 4, 1937, 375-392; Best and Samuel, Ann. Appl. Biol., 23, 1936, 509-537; 759-780; Carter, Phytopath., 29, 1939, 285-287; Lowcock, Queensland Agr. Jour., 48, 1937, 665-672; Linford, *ibid.*, 22, 1932, 301-324; Magee, Agr. Gaz. of New South Wales, 47, 1936, 99-100, 118; McWhorter and Milbrath, Phytopath., 25, 1935, 897-898 (Abst.); Oregon Agr. Exp. Sta., Circ. 128, 1938; Milbrath, Phytopath., 29, 1939, 156-168; Moore, Nature, 147, 1941, 480-481; Moore and Anderssen, Union of So. Africa, Dept. Biol., 20, 1933, 70-99; Jour. Agr. So. Australia, 37, 1933,

190-195; Samuel et al., Coun. Scient. Indus. Res., Austral., Bull. 44, 1930; Ann. Appl. Biol., 22, 1935, 508-524; Shapovalov, Phytopath., 24, 1934, 1149 (Abst.); Smith, Nature, 127, 1931, 852-853; Ann. Appl. Biol., 19, 1932, 305-330; Jour. Minist. Agr., 39, 1933, 1097-1101; Jour. Roy. Hort. Soc., 60, 1935, 301-310; Snyder and Thomas, Hilgardia, 10, 1936, 257-262; Takahashi and Rawlins, Phytopath., 24, 1934, 1111-1115; Taylor and Chamberlain, New Zealand Jour. Agr., 54, 1937, 278-283; Whipple, Phytopath., 28, 1936, 918-920.

Strains: A strain differing somewhat from the type, var. *typicum* H. (*loc. cit.*, 136), has been described as damaging tomatoes in the northwestern United States. It has been given a distinctive varietal name:

1a. *Lethum australiense* var. *lethale* H. (*loc. cit.*, 138). From Latin *lethalis*, deadly. Common names: Tip-blight strain of tomato spotted-wilt virus, Oregon tip-blight virus, tomato die-back streak virus, tomato tip-blight virus. Differs from the type in causing necrotic leaf spotting, stem streaking, and tip blighting in most hosts, without mottling or bronzing of foliage; yet in *Tropaeolum majus* L., there is little necrosis. In tomato, systemic necrosis, terminal shoots blighted and blackened; dead tips stand upright above living foliage. Fruits rough and pitted, with internal pockets of necrotic tissue or with sub-epidermal necrosis, appearing externally as concentric brown bands. (McWhorter and Milbrath, Oregon Agr. Exp. Sta., Circ. 128, 1938; Milbrath, Phytopath., 29, 1939, 156-168.)

## FAMILY VI. LETHACEAE HOLMES.

(Handb. Phytopath. Viruses, 1939, 135.)

Virus strains of the Spotted-Wilt Group, causing diseases characterized by bronzing of foliage, streaking of stems, blighting of tips, necrotic spotting of foliage. Hosts, higher plants; vectors, thrips (*THRIPIDAE*). There is a single genus.

Genus I. *Lethum* Holmes.

(Loc. cit., 135.)

Characters those of the family. Generic name from Latin *lethum*, death. At present there is but one known species, though this is reported to be nearly world-wide in distribution. In some areas it may have been confused with entities needing separate recognition.

The type species is *Lethum australiense* Holmes.

1. *Lethum australlense* Holmes (loc. cit., 136). From Australia, where virus was first described.

Common names: Tomato spotted-wilt virus, bromnek or Kat River disease virus. Also, pineapple yellow-spot or side-rot virus (according to Sakimura, Phytopath., 50, 1940, 281-299).

Hosts. Very numerous species in many families of higher plants. Among those most often noted are *SOLANACEAE*—*Lycopersicon esculentum* Mill., tomato; *Nicotiana tabacum* L., tobacco; *Solanum tuberosum* L., potato. *COMPOSITAE*—*Lactuca sativa* L., lettuce. *LEGUMINOSAE*—*Pisum sativum* L., pea. *BROMELIACEAE*—*Ananas comosus* Merr., pineapple.

Geographical distribution: Australia, British Isles, United States, South Africa, Hawaii, New Zealand, Europe, China, South America.

Induced disease. In tomato, bronze ring-like secondary lesions, plant stunted, some necrosis; later yellowish mosaic with some leaf distortion. Fruit frequently marked with concentric rings of pale red, yellow, or white. In tobacco, primary necrotic lesions followed by systemic necrosis, with stem streak, crook-neck, often stunting with subsequent wilting and death, sometimes temporary recovery followed by recurrence of systemic necrosis. In lettuce, plant yellowed, retarded in growth; brown blem-

ishes in central leaves, affected spots dying, becoming like parchment but with brown margins. Axillary shoots may show chlorotic mottling. In pea, purplish necrotic streaks on stem, at first, leaves mottled; later, necrotic spots damage foliage; pods show circular necrotic spots or wavy lines, or, if severely affected, may collapse; seeds may show necrotic lesions. In potato, zonate necrotic spots on upper leaves, necrotic streaks on stems; stems collapse at top; plant is stunted, yield of tubers small. In pineapple, at first an initial spot or primary lesion  $\frac{1}{4}$  to  $\frac{1}{2}$  inch in diameter, raised, yellowish, on upper surface of young leaf; later chlorotic spotting of young leaves, crook-neck because of necrotic foci in stems and fruits (side rot); plant may die.

Transmission: By inoculation of expressed juice; the addition of fine carborundum powder to inoculum facilitates transmission by rubbing methods. By thrips, *Frankliniella lycopersici* Andre-wartha (formerly identified as *F. insularis* Franklin), *F. occidentalis* Perg., *F. moultoni* Hood. and *F. schultzei* (Trybom) (*THRIPIDAE*). Also by *Thrips tabaci* Lind. (*THRIPIDAE*). In *F. lycopersici*, thrips must pick up virus while still a nymph; virus persists through pupation and emergence as adult; preinfective period in vector, 5 to 9 days. Virus is not transmitted through eggs of

Aerobic, facultative.

Optimum temperature 20° to 25°C.

Habitat: Water.

36 *Pseudomonas punctata* (Zimmermann) Chester. (*Bacillus punctatus* Zimmermann, Bakt. unserer Trink- und Nutzwässer, Chemnitz, 1, 1890, 38; *Bacillus aquatilis communis* Kruse, in Flüge, Die Mikroorganismen, 2, 1896, 315; *Bacterium punctatum* Lehmann and Neumann, Bakt. Diag., 1 Aufl., 2, 1896, 238; Chester, Man. Determ. Bact., 1901, 313; *Achromobacter punctatum* Bergey et al., Manual, 1st ed., 1923, 147.) From Latin, *punctus*, a puncture, point; M. L. *punctata*, dotted.

Rods: 0.7 by 1.0 to 1.5 micron, occurring singly, in pairs and in chains. Motile with a single polar flagellum. Gram-negative.

Gelatin colonies: Small, circular, gray, arose to filamentous, punctiform.

Gelatin stab: Crateriform liquefaction. No pellicle.

Agar slant: Gray, smooth, filamentous.

Broth: Turbid with delicate pellicle.

Litmus milk. Acid; coagulated; peptonized.

Potato: Brownish-yellow to brownish-red color.

Indole is formed.

Nitrites not produced from nitrates.

Hydrogen sulfide is formed.

Acid and gas from glucose.

*philus* Chester, Manual Determ. Bact., 1901, 235; *Bacterium hydrophilum* Weldin and Levine, Bact. Abs., 7, 1923, 14; *Proteus hydrophilus* Bergey et al., Manual, 1st ed., 1923, 211; *Aeromonas hydrophila* Stanier, Jour. Bact., 46, 1943, 213 } From Greek, *hydro*, water, *philus*, loving; M. L. water-loving.

It was reported by Russell, Jour. Amer. Med. Assoc., 30, 1895, 1442 and later by Emerson and Norris, Jour. Exper. Med., 7, 1905, 32 who made a complete study of its properties and its pathogenic action.

Weldin (Iowa State College Jour. Sci., 1, 1927, 151) considers *Bacillus ranicida* Ernst (Beiträge z. path. Anat. u. z. Allgemein. Pathol., 8, 1890, 204; *Bacterium ranicida* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., 9, 1897, 141) a possible synonym of *Proteus hydrophilus*.

Rods: 0.6 by 1.3 microns, occurring singly and in chains. Motile, with a single polar flagellum (Kulp and Borden, Jour. of Bact., 44, 1942, 673). Gram-negative.

Gelatin colonies: Small, circular, gray, translucent, stippled.

Gelatin stab: Napiform liquefaction.

Agar colonies: Whitish, raised, moist, stippled.

Agar slant: Thin, whitish, glassy, spreading, becoming yellowish.

Broth: Turbid, with heavy pellicle.

Litmus milk: Acid; coagulated; peptonized.

## SUBORDER III. Zoophaginae subordo novus.

From Greek *phagein*, to eat, and *zoon*, an animal. Viruses infecting animals but having no plant hosts, so far as known.

## Key to the families of suborder Zoophaginae.

- 1 Inducing diseases in insects as exclusive hosts.

Family I. *Borrelinaceae*, p. 1225.

- 2 Inducing diseases of the pox group

Family II. *Borreliotaceae*, p. 1229.

3. " " " " " "

4

Family IV. *Charonaceae*, p. 1265.

- 5 Inducing diseases of the infectious anemia group

Family V. *Trifuraceae*, p. 1282

6. Inducing diseases of the mumps group

Family VI. *Rabulaceae*, p. 1284.

## FAMILY I. BORRELINACEAE FAM. NOV.

Viruses causing polyhedral, wilt, and other diseases in arthropods. The genus *Borrelina* Paillot was originally spelled *Borrellina* by error; from Borrel, name of French scientist.

## Key to the genera of family Borrellinaceae.

- I. Known only as attacking lepidopterous insects.

Genus I. *Borrelina*, p. 1225.

- II. Known only as attacking the honey bee, a hymenopterous insect.

Genus II. *Morator*, p. 1227.

Genus I. *Borrellina* Paillot.

(Compt. rend. Acad. Sci., Paris, 182, 1926, 182.)

Viruses inducing polyhedral, wilt, and other diseases; hosts, Lepidoptera, so far as known.

The type species is *Borrellina bombycis* Paillot.

Key to the species of genus *Borrellina*.

- I Attacking silkworm.

1. *Borrellina bombycis*.

- II. Attacking nun moth.

2. *Borrellina efficiens*.

- III. Attacking gypsy moth.

3. *Borrellina reprimens*.

- IV. Attacking cabbage worm.

4. *Borrellina brassicae*.

5. *Borrellina pieris*.

1. *Borrelina bombycis* Paillot. (Compt. rend. Acad. Sci., Paris, 182, 1926, 182.) From Latin *bombyx*, silk-worm. (Note: Coccus-like bodies surrounded by non-staining substances, associated with the induced disease, received the provisional name *Chlamydozoon bombycis* from Prowazek, Arch. f. Protistenkunde, 10, 1907, 363.)

Common names: Silkworm-jaundice virus, silkworm-grasserie virus, silkworm wilt virus, Gelbsucht virus, Fettsucht virus.

Host: *BOMBYCIDAE*—*Bombyx mori* (L.), silkworm.

Geographical distribution: Japan, Italy, France.

Induced disease: In silkworm, after prodromal period of 5 days or more, yellow spots on skin, polyhedral bodies in blood, inactivity, loss of appetite, irritability, weakening of body facilitating rupture from mechanical stress, eventual death.

Transmission: By feeding. Experimentally, also by injection.

Serological relationships: Specific agglutination, precipitation, and complement fixation.

Thermal inactivation: At 60° C in 15 to 20 minutes in blood.

Filterability: Passes Berkefeld N and V, Chamberland L<sub>1</sub>, L<sub>2</sub>, and L<sub>3</sub> filters.

Other properties: May survive at least 2 years in dry state. Stable between pH 5 and about pH 9. Sedimentation constant 17 S.

Literature: Aoki and Chigasaki, Cent. f. Bakt., I Abt., Orig., 86, 1921, 481-485; Glaser and Lacaille, Am. Jour. Hyg., 20, 1934, 454-464; Glaser and Stanley, Jour. Exp. Med., 77, 1943, 451-466; v. Prowazek, Cent. f. Bakt., I Abt., Orig., 67, 1912, 268-284; Suzuki, Bull. Imperial Kyoto Sericultural College, 1, 1929, 45-75; Trager, Jour. Exp. Med., 61, 1935, 501-513.

2. *Borrelina efficiens* spec. nov. From

Latin *efficiens*, effective, in reference to effectiveness of this virus in controlling nun-moth infestations.

Common names: Nun-moth disease virus, nun-moth wilt virus, Wipfelkrankheit virus.

Host: *LYMANTRIIDAE*—*Lymantria monacha* (L.), nun moth.

Geographical distribution: Europe.

Induced disease: In eggs, larvae, pupae and occasionally adults of nun moth, polyhedral bodies in affected tissues. Blood of sick larvae turbid; later, blood cells few; contents of body finally become a gray-brown, semifluid mass.

Transmission: By feeding.

Thermal inactivation: At 55 to 60° C in 5 to 10 minutes.

Filterability: Fails to pass Berkefeld and Chamberland filters.

Other properties: May remain viable at least 2 years in dry state.

Literature: Escherich and Miyajima, Naturwissens. Ztschr. f. Forst- u. Landwirtschaft, 9, 1911, 381-402; Wachtl and Kornauth, Mitth. a. d. forstl. Versuchswesen Österreichs, 16, 1893, 1-35; Wahl, Centralbl. Gesam. Forstw., 35, 1903, 164-172; 212-215; 36, 1910, 377-397; 37, 1911, 247-268; 38, 1912, 353-378.

3. *Borrelina reprimens* spec. nov. From Latin *reprimere*, to restrain.

Common name: Gypsy-moth wilt virus.

Host: *LYMANTRIIDAE*—*Porthetria dispar* (L.), gypsy moth.

Geographical distribution: United States.

Induced disease: In gypsy moth caterpillar, flaccidity, disintegration of tissues, eventual collapse as a watery sack. Death occurs in 13 to 29 (average 21) days after infection; caterpillar may remain attached to its support by prolegs; skin ruptures easily. Polyhedral bodies originate in nuclei of the tracheal matrix, hypodermal, fat, and blood cells.

Transmission: By feeding on contam-

inated foliage. Not through undamaged skin.

Filterability: Passes Berkefeld N, not Pasteur-Chamberland F, filter.

Literature: Chapman and Glaser, Jour. Econ. Entomol., 8, 1915, 140-150; 9, 1916, 149-167; Glaser, Jour. Agr. Res., 4, 1915, 101-128; Science, 48, 1918, 301-302; Glaser and Chapman, Jour. Econ. Entomol., 8, 1913, 479-485

4. *Borrelina brassicae* Paillot. (Compt. rend. Acad. Sci., Paris, 182, 1926, 182.) From name of host, *Pieris brassicae*.

Common name: Cabbage-worm grass-erie virus.

Host: *PIERIDAE*—*Pieris brassicae* (L.), cabbage worm.

Induced disease: In cabbage worm, nuclear or cytoplasmic inclusions; nucleus of fat and hypodermal cells hypertrophied and soon disorganized.

Transmission: By feeding.

Other properties. Described microscopic in size, intracytoplasmic.

Appendix: *Borrelina flachei* 535 pp., Trévoux, Patissier, 1933.

535 pp., Trévoux, Patissier, 1933. *Mori* L. No previous reference.

Genus 11. *Mori* of this species has been found.

Only one species at present, inducing the bee. Generic name from Latin *moriator*, to gen. nov.

*Moriator acetabulae* spec. nov.

1. *Moriator acetabulae* spec. nov. From Latin *acetabula*, early period of life, in reference to attack on immature stages of host, exclusively.

Common name Honey bee sacbrood virus.

Host: *APIDAE*—*Apis mellifera* L., honey bee (immature stages only).

Insusceptible species *LYMANTRIIDAE*—*Parthetia dispar* (L.), gypsy moth.

Geographical distribution: United States.

Literature: Paillot, loc. cit.; Ann. Inst. Pasteur, 40, 1926, 314-452; L'infection chez les insectes. Immunité et symbiose, 535 pages, Trévoux, Patissier, 1933.

5. *Borrelina pieris* Paillot. (Compt. rend. Acad. Sci., Paris, 182, 1926, 182.) From New Latin *Pieris*, generic name of host.

Common name: Virus of nuclear disease of pierids.

Host: *PIERIDAE*—*Pieris brassicae* (L.), cabbage worm.

Induced disease: In cabbage worm, body yellowish below, tears easily just before death; chromatin of nuclei in fat and blood cells condensed in irregular masses; cytoplasmic inclusions staining faintly red in Giemsa preparations.

Transmission: By feeding

Other properties: Described as intracytoplasmic, less than 0.1 micron in diameter

Literature: Paillot, loc. cit.; Ann. Inst. Pasteur, 40, 1926, 314-452; L'infection chez les insectes. Immunité et symbiose, 535 pages, Trévoux, Patissier, 1933.

Genus 11. *Mori* of this species has been found.

like mass without rupture; contents watery with many suspended, fine, brown particles. There are no characteristic intracellular bodies in affected tissues. Dead larvae eventually dry down to form scales that are black and roughened, that separate readily from the cell wall, and that may be lifted out intact. Colonies tend to lose virus spontaneously.

Transmission: By contamination of food. Not by hands, clothing, or tools. Perhaps through water supply of insects.

Thermal inactivation: In water, at 58°

C in 10 minutes. In honey, at 70 to 73° C in 10 minutes.

Filterability: Passes Berkefeld and Pasteur-Chamberland filters.

Other properties: Withstands drying 20, not 22, days, exposure to sunlight 7 hours or less, storage in honey a month or more,  $\frac{1}{4}$  to 2 per cent aqueous solutions of carbolic acid 3 weeks or more.

Literature: McCray and White, U. S. Dept. Agr., Dept. Bull. 671, 1918; White, U. S. Dept. Agr., Bur. of Entomol., Circ. 169, 1913; U. S. Dept. Agr., Dept. Bull. 92, 1914; *ibid.*, Dept. Bull. 431, 1917.

## FAMILY II. BORRELIOTACEAE FAM. NOV.

Viruses of the Pox Group, inducing diseases characterized in general by discrete primary and secondary lesions of the nature of macules, papules, vesicles, or pustules.

*Key to the genera of family Borreliotaceae.*

- I. Viruses of the Typical Pox-Disease Group.  
Genus I. *Borreliota*, p 1229.
- II. Viruses of the Varicella Group  
Genus II. *Briareus*, p 1233
- III Viruses of the Herpes Group.  
Genus III. *Scelus*, p. 1234.
- IV. Viruses of the Foot-and-Mouth-Disease Group.  
Genus IV. *Hostis*, p. 1239
- V. Viruses of the Wart-Disease Group.  
Genus V. *Molitor*, p 1240.

*Genus I Borreliota Goodpasture.*

(Science, 77, 1933, 121.)

Viruses of the Typical Pox-Disease Group, inducing diseases characterized by formation of papules, pustules, and scabs, shed with or without scarring. Generic name from *Borrel*, investigator who first discovered the specific granules of fowl pox and Latinized name of the smallest Greek letter, *iota*, signifying smallest particle. The name *Cytoryctes variolae* Guarnieri 1892 was based on intracellular inclusions, Guarnieri bodies, as supposed sporozoan parasites (Calkins, Jour. Med. Res., 11, 1904, 136-172).

The type species is *Borreliota avium* Goodpasture.

*Key to the species of genus Borreliota.*

- I. Affecting domestic fowl.
  - 1. *Borreliota avium*.
- II Affecting man principally, although strains have become adapted to cow, rabbit, etc.
  - 2 *Borreliota variolae*.
- III Affecting swine.
  - 3. *Borreliota suis*.

1 *Borreliota avium* (Lipschütz) Goodpasture. (*Strongyloplasma avium* Lipschütz, in Kofle, Kraus and Uhlenhuth, Handbuch der pathogenen Mikroorganismen, 3 Aufl., 8, 1930, 314, Goodpasture, Science, 77, 1933, 121) From Latin *aves*, fowl of the air.

Common names: Fowl-pox virus; also known as poultry-pox virus, chicken-pox virus (but not the virus of the same name attacking man rather than the chicken), or virus of epitheloma contagiosum of fowls; strains have been studied under

the names Kikuth's canary virus and pigeon-pox virus.

Hosts: Chicken, turkey, pigeon, goose, duck, guinea fowl, quail, hawk, pheasant, partridge, bunting sparrow, canary. Experimentally, also English sparrow, chick embryo.

Insusceptible species: Man, goat, sheep, mouse, rat, guinea pig.

Geographical distribution: Europe, Asia, North America; perhaps coextensive with the area in which chickens are grown under conditions of domestication.

**Induced disease:** In chicken, hyperplastic nodular lesions of the skin, diphtheritic membranes in mouth and throat, discharges from eyes and nose; nodules eventually dry up and fall off, usually without leaving scars. Inclusion bodies, known as Bollinger bodies, believed to represent aggregates of minute Borrel bodies or virus particles, leave much grayish-white ash when incinerated; break readily after digestion by 1 per cent trypsin in 0.2 per cent sodium bicarbonate. Borrel bodies coccoid, 0.25 microns in diameter. On chorioallantoic membrane of chick embryo, proliferation and hyperplasia, or necrosis.

**Transmission:** By contact, perhaps through wound infection. By blood-sucking dipterous insects. Experimentally, by scarification of skin or buccal mucosa; by intravenous, intradermal, subcutaneous, intramuscular, or intraperitoneal inoculation. May be passed in series by nasal instillation in chickens, obvious mucosal changes occurring only occasionally. Experimentally, by mosquitoes (*CULICIDAE*), *Aedes aegypti* L., *A. stimulans* Walker, *A. vexans* Meigen (as long as 27 days from time of feeding on infective material), and *Culex pipiens* L. (indefinitely after infective feeding, as long as the individual mosquito lives); in *C. pipiens*, the virus has been found also under natural conditions.

**Serological relationships:** Neutralizing and elementary-body-agglutinating antisera specific. Antivaccinal serum from rabbit ineffective against fowl-pox virus, although neutralizing vaccinia virus.

**Immunological relationships:** No cross immunity with respect to vaccinia virus in the chicken.

**Thermal inactivation:** At 60° C in 8 minutes; at 56° C in 30 minutes.

**Filterability:** Passes Berkefeld V, not Chamberland L, filter candle.

**Other properties:** Drying at room temperature *in vacuo* does not inactivate. Viable after storage at least 24 months at 0 to 4° C, dry.

**Strains:** A strain known as Kikuth's

canary virus has been studied in some detail. When introduced into the rabbit it induces formation of neutralizing antibodies that react strongly with homologous virus, moderately against fowl-pox virus. Antivaccinal serum is ineffective against it. In canaries, it induces proliferation of dermal epithelium with cytoplasmic inclusions, the inflammatory process being characterized by predominantly mononuclear cells with vacuolated cytoplasm; in the lung there is massive accumulation of large mononuclear cells containing the specific cytoplasmic inclusions; the disease is regularly fatal. Passes Berkefeld N filter. Size estimated as 120 millimicrons by centrifugation. (Bechhold and Schlesinger, *Zschr. f. Hyg.*, 116, 1933, 354-357; Burnet, *Jour. Path. and Bact.*, 57, 1933, 107-122; Burnet and Lush, *Brit. Jour. Exp. Path.*, 17, 1936, 302-307; Gaede, *Cent. f. Bakt.*, I Abt., Orig., 155, 1935, 342-346; Kikuth and Gollub, *ibid.*, 125, 1932, 313-320.)

**Literature:** Andervont, *Am. Jour. Hyg.*, 6, 1926, 719-751; Brandly and Dunlap, *Jour. Am. Vet. Med. Assoc.*, 35, 1939, 340-349; Brandly et al., *Am. Jour. Vet. Res.*, 2, 1941, 190-192; Brody, *Cornell Agr. Exp. Sta. (Ithaca). Memoir* 195, 1936; Buddingh, *Jour. Exp. Med.*, 67, 1938, 933-940; Burnet and Lush, *Brit. Jour. Exp. Path.*, 17, 1936, 302-307; Danks, *Am. Jour. Path.*, 8, 1932, 711-716; Findlay, *Proc. Roy. Soc. London, Ser. B*, 102, 1928, 351-379; Goodpasture and A. M. Woodruff, *Am. Jour. Path.*, 6, 1930, 699-712; Goodpasture and C. E. Woodruff, *ibid.*, 7, 1931, 1-8; Irons, *Am. Jour. Hyg.*, 40, 1934, 329-351; Kligler and Ashner, *Proc. Soc. Exp. Biol. and Med.*, 28, 1931, 463-465; Kligler et al., *Jour. Exp. Med.*, 49, 1929, 649-660; Ledingham, *Lancet*, 221, 1931 (2), 525-526; Ludford and Findlay, *Brit. Jour. Exp. Path.*, 7, 1926, 256-264; Matheson et al., *Poultry Science*, 10, 1931, 211-223; Megrill, *Am. Jour. Hyg.*, 9, 1929, 462-465; Nelson, *Jour. Exp. Med.*, 74, 1911, 203-212; A. M. Woodruff, and Goodpasture, *Am. Jour.*

Path., 7, 1931, 209-222; C. E. Woodruff, *ibid.*, 8, 1930, 169-174; C. E. Woodruff, and Goodpasture, *ibid.*, 8, 1929, 1-10, 6, 1930, 713-720.

2. *Borrelliota variolae* (Lipschütz) Goodpasture. (*Strongyloplasma variolae* Lipschütz, in Kolle, Kraus and Uhlenhuth, *Handbuch der pathogenen Mikroorganismen*, 3 Aufl., 8, 1930, 317; Goodpasture, *Science*, 77, 1933, 121.) From New Latin *variola*, smallpox.

Common names: Variola virus, smallpox virus. Most studies of this virus have been concerned with the vaccinia strain; see Strains below.

Hosts: Man, cow and rabbit are susceptible to strains that appear especially adapted to them (see Strains below). Experimentally, also chicken (and chick embryo), *Chrysemys marginata*, turtle, guinea pig, horse, pig, *Macaca mulatta* (Zimmermann), rhesus monkey, *M. irus*, cynomolgus monkey, orang-outang; *Macacus fuscatus*.

Geographical distribution: Nearly world-wide, except where excluded by isolation or protective vaccination.

Induced disease: In man, mild to severe smallpox, sometimes with poxæ few and discrete but often with poxæ numerous and coalescing, onset sudden, 6 to 22 days (average 12) after infection, headache, vomiting, fever, often rashes on body before appearance of the specific eruption, bright red spots becoming vesicular and eventually pustular, the poxæ are commonest on face, forearms, wrists, palms of hands, and soles of feet; pustules gradually become flattened scabs and drop off, leaving no scar if superficial and not secondarily infected; in hemorrhagic smallpox there are numerous hemorrhages into the skin and mortality is high, death often preceding formation of pustules; severity of disease and mortality roughly proportional to the amount of eruption on the face.

Transmission: By contact with infected individuals or contaminated articles, perhaps by droplet infection,

obvious primary lesions characterizing experimental transmission by scarification but not natural spread.

Serological relationships: Hyperimmune calf serum neutralizes virus. Neutralization depends on an antibody not involved in agglutination and precipitation. Antivaccinial serum gives complement fixation in the presence of variola virus. One agglutinin (L) labile at 56° C, one (S) stable at 95° C; both are parts of a single protein but can be degraded independently; chymotrypsin destroys activity of S, not L. Increasing neutralization in immune serum and virus mixtures *in vitro* with progressive incubation; partial reactivation on simple dilution. Antivaccinial sera agglutinate Paschen bodies of vaccinia but not Borrel bodies of fowl pox; anti-fowl-pox sera agglutinate Borrel but not Paschen bodies. No cross reactions with herpes virus.

Immunological relationships: In vaccinia-immune swine, protective substances pass *via* colostrum, conveying passive immunity to young for 2 to 3 months after birth. In man, immunity against variola virus is conferred by earlier infection with vaccinia strain. In hen, previous infection with fowl-pox virus does not immunize with respect to vaccinia virus.

Thermal inactivation: At 55° C in 20 minutes.

Filterability: Passes Berkefeld V, not Mandler, filter.

Other properties: Density about 1.16. Sedimentation constant  $5000 \times 10^{-13}$  (corrected to water at 20° C). Retains activity in glycerine best at pH 7.0. 0.1 per cent gelatin delays spontaneous inactivation at 5 to 10° C. Withstands absolute alcohol, ether, acetone, and petroleum ether 1 hour in dry samples at 4° C without decrease in activity. Inactivated without disruption by sonic vibrations of about 5900 cycles per second. Diameter estimated as 125 to 175 microns by filtration; 236 to 232 microns by ultracentrifugation. Electron micrographs show limiting surface

membrane, dense granules (usually 5) within; tendency to rectangular outlines with rounded corners. At least 5.6 per cent of virus is reported to be thymonucleic acid. Contains nitrogen, 15.3 per cent; carbon, 33.7 per cent; phosphorus, 0.57 per cent; phospholipid (lecithin), 2.2 per cent; neutral fat, 2.2 per cent; reducing sugars after hydrolysis, 2.8 per cent; cystine, 1.9 per cent; copper, 0.05 per cent.

Strains: Besides the typical variola strain, var. *hominis* Goodpasture (Science, 77, 1933, 121), several distinctive strains have been studied. A spontaneous cowpox strain differs in some antigens but affords cross immunity with respect to var. *bovis* Goodpasture (*loc. cit.*, 121), vaccinia virus, which in turn immunizes against typical variola virus. A spontaneous rabbit-pox strain, serologically resembling neurovaccine virus, is believed to exist independently in Europe and the United States. The varieties *equi* (horse-pox virus), *porci* (swine strain), and *ovium* (sheep and goat pox virus) have been attributed to this species by Goodpasture (*loc. cit.*, 121). The alastrim strain (causing *variola minor*) differs from the type in producing a relatively mild disease in man and in inducing the formation of a distinctive type of intracellular inclusion in affected tissues.

Exp. Med., 50, 1929, 31-40.

3. *Borreliota suis spec. nov.* From Latin *suis*, swine.

Common name: Swine-pox virus (not

the vaccinia strain of variola virus in swine).

Host *SUIDAE*—*Sus scrofa* L., domestic swine.

Insusceptible species: Rabbit.

Geographical distribution: United States (Iowa).

Induced disease: In swine, locally, reddened hyperemic papules 3 to 7 mm in diameter; papules become briefly vesicular, then change gradually to true pustules, finally forming dark brown to blackish scabs which are shed after a few weeks without scarring; no secondary lesions in hogs free from lice, but in infested animals numerous secondary lesions appear 1 to 2 weeks after primary lesions and are commonly most numerous in the inguinal and axillary regions. Mortality negligible but growth retarded.

Virus has been recovered from hog louse after feeding on affected swine.

Transmission: By hog louse, *Haematopinus suis* (*HAEMATOPINIDAE*), probably mechanically. By experimental scarification of skin.

Serological relationships. No reaction with neutralizing sera specific for vaccinia virus.

Immunological relationships: Specific immunity in swine after attack, but no cross immunity with respect to vaccinia virus.

Filterability: Passes Berkefeld V and N filters.

Literature: Csontos and von Nyiredy, *Deutsch tierärztl. Wchnschr.*, 41, 1933, 529-532, Schwarte and Diester, *Am. Jour. Vet. Res.*, 2, 1941, 136-140, Shope, *Arch. f. Virusforsch.*, 1, 1940, 457-467.

### Genus II. *Briareus* gen. nov.

Viruses of the Varicella Group, causing diseases characterized by reddened spots and rings in affected tissues, becoming papular or vesicular. Generic name from Latin *Briareus*, name of a hundred-armed giant.

The type species is *Briareus varicellae* spec. nov.

#### Key to the species of genus *Briareus*.

##### I. Causing chicken pox and herpes zoster in man

###### 1. *Briareus varicellae*.

##### II. Causing measles in man.

###### 2. *Briareus morbillorum*.

1 *Briareus varicellae* spec. nov. From New Latin *varicella*, chicken pox.

Common names: Varicella virus, chicken pox virus, much evidence for identity with so-called herpes-zoster virus has been presented.

Host *HOMINIDAE*—*Homo sapiens* L., man

Insusceptible species: Chick embryo.

Geographical distribution: World-wide.

Induced disease: In man, usually abrupt onset, rash at first macular, soon papular and vesicular; vesicles generally discrete, soon rupturing, healing with scab formation and itching; separation of deeper scales may leave persistent scars; in severe cases there may be stomatitis, laryngitis, and nasal lesions. In human skin grafted on chorionallantois of chick

embryo, experimentally, pustular lesions as in natural disease, with intranuclear acidophilic inclusions, no gross vesiculation

Transmission: By contact. By spread of droplets. Children in contact with herpes zoster patients sometimes contract varicella

Serological relationships: Majority of herpes zoster sera that agglutinate zoster antigen also agglutinate elementary bodies of varicella; complement fixation tests also indicate relationship of virus from herpes zoster and varicella. Chicken-pox sera do not flocculate smallpox brain-virus antigen.

Immunological relationships: Children previously having varicella are immune to inoculation with herpes zoster virus.

Literature: Amies, Brit. Jour. Exp. Path., 15, 1934, 314-320; Brain, *ibid.*, 14, 1933, 67-73; Bruusgaard, Brit. Jour. Derm. Syph., 44, 1932, 1-24; Goodpasture and Anderson, Am. Jour. Path., 20, 1944, 447-453; Havens and Mayfield, Jour. Inf. Dis., 50, 1932, 242-248; Irons et al., Am. Jour. Hyg., 33, (B), 1941, 50-55; Kundratitz, Monatsschr. Kinderheilk., 29, 1925, 516-523; Lipschütz and Kundratitz, Wien. klin. Woch., 58, 1925, 499-503.

2. *Briareus morbillorum spec. nov.*  
From New Latin *morbilli*, measles.

Common name: Measles virus.

Host: *HOMINIDAE*—*Homo sapiens* L., man. Experimentally, also *CERCOPITHECIDAE*—*Macaca mulatta* (Zimmermann), rhesus monkey. *PHASI-ANIDAE*—*Gallus gallus* (L.), chick embryo (no lesions, but 30 serial passages).

Geographical distribution: World-wide except in isolated communities.

Induced disease: In man, after incubation period of 7 to 21 days, bright red spots on buccal mucosa, especially near first molar tooth (Koplik's spots) followed by rash on face, head, neck, then arms,

trunk, and legs; papules often crescents, lesions usually discrete; rash fades, leaving brownish discoloration and desquamation.

Transmission: By contact. By droplets.

Serological relationships: Convalescent serum is reported to modify the course of the induced disease if administered intravenously in the preeruptive stage.

Immunological relationships: Specific immunity in man after attack.

Thermal inactivation: At 55° C in 15 minutes.

Filterability: Passes Berkefeld N filter candle and Seitz EK disks.

Other properties: Viable at -35° C for at least 4 weeks. Not inactivated by 10 per cent anesthetic ether in 40 minutes.

Literature: Blake and Trask, Jour. Exp. Med., 33, 1921, 385-412; Gordon and Knighton, Am. Jour. Path., 17, 1941, 163-176; Hedrich, Am. Jour. Hyg., 17, 1933, 613-636; Kohn et al., Jour. Am. Med. Assoc., 111, 1938, 2361-2364; Rake and Shaffer, Jour. Immunol., 33, 1940, 177-200; Rake et al., Jour. Inf. Dis., 69, 1941, 65-69; Scott and Sunon, Am. Jour. Hyg., 6, 1925, 109-126.

### Genus III. *Scelus gen. nov.*

Viruses of the Herpes Group, inducing diseases characterized in general by vesicular primary lesions, sometimes with subsequent involvement of the nervous system. Generic name from Latin *scelus*, rascal.

The type species is *Scelus recurrens spec. nov.*

#### Key to the species of genus *Scelus*.

- |     |  |                              |
|-----|--|------------------------------|
| I   | In man, cause of so-called fever blisters, herpes febrilis | 1. <i>Scelus recurrens</i> . |

mice, guinea pigs and rabbits, causing hemorrhagic septicemia

Distinctive characters. Much like *Pseudomonas punctata* (Guthrie and Hitchner, Jour. Bact., 45, 1943, 52).

Source: Isolated from frogs dead of septicemia (red leg).

Habitat: Water and infected fresh water animals.

38. *Pseudomonas ichthyosmia* (Hammer) comb. nov. (*Bacillus ichthyosmius* Hammer, Iowa Agr Sta Res Bul 38, 1917; *Escherichia ichthyosmia* Bergey et al., Manual, 1st ed., 1923, 201, *Proteus ichthyosmius* Bergey et al., Manual, 4th ed., 1931, 364) From Greek, *ichthys*, a fish; *osmē*, an odor.

Rods: 0.6 to 0.8 by 1.0 to 2.1 microns, occur singly. Motile with a single polar flagellum (Breed). Gram-negative

Gelatin stab: Liquefaction

Agar colonies: Small, white, becoming darker with age.

Agar slant: Dirty white, viscous growth

Broth: Turbid with gray sediment

Litmus milk: Acid Litmus reduced

Cultures have fishy odor

Potato: Thin, glistening layer

Indole is formed.

Nitrites produced from nitrates

Acid and gas from glucose, fructose, galactose, maltose, sucrose, glycerol, salicin and mannitol. Lactose, dulcitol, raffinose and inulin not fermented

Aerobic, facultative.

Optimum temperature 20°C

Source: Isolated from can of evaporated milk having a fishy odor.

Habitat: Not known.

39. *Pseudomonas ambigua* (Wright) Chester. (*Bacillus ambiguus* Wright, Memoirs Nat. Acad. Sci., 7, 1895, 439, Chester, Man. Determ. Bact., 1901, 308; *Achromobacter ambiguus* Bergey et al., Manual, 1st ed., 1923, 148) From Latin, *ambiguus*, doubtful, uncertain.

Small rods, with rounded ends, occurring singly, in pairs and in chains Mo-

tile, possessing a polar flagellum. Gram-negative.

Gelatin colonies: Gray, translucent, slightly raised, irregular, radiate, with transparent margin.

Gelatin stab: No liquefaction.

Agar slant: Gray, limited, entire.

Broth: Turbid, with gray sediment.

Litmus milk: Acid, slowly coagulated.

Potato: Gray to creamy, viscid, spreading.

Indole is formed.

Nitrites not produced from nitrates.

Aerobic, facultative.

Optimum temperature 30° to 35°C.

Habitat: Water.

40. *Pseudomonas sinuosa* (Wright) Chester (*Bacillus sinuosus* Wright, Memoirs Nat. Acad. Sci., 7, 1895, 440; Chester, Man. Determ. Bact., 1901, 307; *Achromobacter sinosum* (sic) Bergey et al., Manual, 1st ed., 1923, 148.) From Latin, *sinuosus*, full of bends, sinuous

Medium-sized rods, with rounded ends, occurring singly, in pairs and in chains. Motile, possessing two to four polar flagella Gram-negative.

Gelatin colonies: Thin, translucent, irregular, center brownish.

Gelatin stab: Grayish-white, glistening, translucent No liquefaction.

Agar slant: Scanty, grayish growth.

Broth: Turbid, with gray sediment.

Litmus milk: Unchanged.

Potato: Grayish-white, moist, spreading.

Indole is formed.

Nitrites not produced from nitrates.

Aerobic, facultative

Optimum temperature 30° to 35°C.

Habitat: Water.

41 *Pseudomonas cruciviae* Gray and Thornton (Gray and Thornton, Cent. f. Bakt., II Abt., 73, 1928, 91; *Achromobacter cruciviae* Bergey et al., Manual, 3rd ed., 1930, 218) From Latin, *crux*, a cross, *via*, way, road; from Waycross, a place name.

2. *Scelus sullum* spcc. nov. From Latin *sullus*, pertaining to swine.
- Common names: Pseudorabies virus, mad-itch virus.
- Hosts: Domestic cattle, swine, dog, cat, horse, sheep. Experimentally, also rabbit, guinea pig, white rat, white mouse, gray field mouse, duck, chicken, chick embryo; *Macaca mulatta* (Zimmermann), rhesus monkey.
- Geographical distribution: France, Germany, Hungary, Holland, Denmark, Switzerland, Siberia, Brazil, United States.
- Induced disease: In cattle, licking of affected area, usually somewhere on hind-quarters, sudden decrease in milk production in dairy animals, violent rubbing, biting, and gnawing of lesion; swelling and discoloration of affected parts with oozing of serosanguineous fluid; grinding of teeth and excessive salivation in some individuals; death, preceded by clonic convulsions, violent tossing of head, and shallow respiration, usually 36 to 48 hours after onset. In pig, mild but highly contagious disease; slight nerve-cell degeneration, predominance of vascular and interstitial lesions.
- Transmission: By contact in swine, not in cattle. By feeding in cats, brown rats, and swine.
- Serological relationships: Cross neutralization between constituent strains. Anti-herpes sera protect in some cases against small, but constantly infective, doses of pseudorabies virus.
- Literature: Aujeszky, Cent. f. Bakt. I Abt., Orig., 32, 1902, 353-357; F. B. Bang, Jour. Exp. Med., 76, 1942, 263-270;

1. *Scelus recurrens spec. nov.* From Latin *recurrere*, to recur. Note: The name *Neurocystis herpetii* Levaditi and Schoen (Compt. rend. Soc. Biol., Paris, 96, 1927, 961) was applied provisionally to the causative microorganism of herpes, in the expectation that future research would show inclusion bodies in affected tissues to be stages in its life cycle.

Common names: Herpes virus, virus of herpes simplex, virus of herpes febrilis (not herpes zoster virus, for which see varicella virus), virus of keratitis dendritica, virus of aphthous stomatitis (of man).

Host. *HOMINIDAE*—*Homo sapiens* L., man. Experimentally, also rabbit, guinea pig, white mouse, cat, goose, hedgehog, and, though difficult to infect, dog and pigeon. Chick embryo (but not chicken). Also *CERCOPITHECIDAE*—*Cercopithecus fuliginosus* E. Geoffroy, *Macacus cynomolgus*. *CEBIDAE*—*Cebus olivaceus*.

Insusceptible species: White rat, *Bufo viridis*; *Cercopithecus callithrix*; chicken (except embryo).

Geographical distribution: Probably world-wide.

Induced disease. In man, usually acquired in first three years of life, sometimes as aphthous stomatitis; virus probably retained often through life, sometimes with periodic reappearance of dermal lesions, which are vesicular and heal soon. In white mouse, by experimental inoculation of skin, small inflamed vesicular primary lesions about 5 days after inoculation, usually forming scabs and healing a few days later, but sometimes persisting, if on tail, followed by swelling and paralysis of tail, ascending paralysis and death, or by recovery with acquired immunity, if near head, followed by encephalitis and death, intraperitoneal and sometimes other inoculations immunize, relapse with recurrence of primary lesions rare. In chick embryo, white, opaque, circular or ring like primary lesions of small size on chorionallantoic membrane, with or without necrotic secondary lesions in liver, heart, lungs, spleen, and

kidneys; virus enters membrane 1 to 4 hours after it is dropped on its surface; primary lesions may be counted in 48 hours.

Transmission: By contacts. Experimentally, by skin scarification; in guinea pig, by feeding.

Serological relationships: Distant relationship to pseudorabies virus, *Scelus suillum*, shown by moderate protection against this virus conferred by some anti-herpes sera. No relationship to vaccinia virus or to virus III of rabbits demonstrable by neutralization tests. Specific complement fixation. Neutralizing antibody forms reversible union with virus, at least for a time, though with strong mixtures partial irreversibility finally occurs.

Immunological relationships: Formalized virus and non-lethal strains of virus immunize specifically. No cross immunity with vaccinia virus.

Thermal inactivation: At 50 to 52° C in 30 minutes, when moist, at 90 to 100° C in 30 minutes, when dry. At 41.5° C in 50 to 80 hours.

Filterability: Passes Berkefeld V filter with slight loss.

Other properties: Diameter, by centrifugation, computed as 180 to 220 millimicrons; by filtration, 100 to 150 millimicrons. Specific gravity, 1.15. Inactivated by repeated freezing and thawing, also by pressure of 3000 atmospheres for 30 minutes. Viable dry at least 18 months at 4° C, in 50 per cent glycerine at least 6 months. Not inactivated at 4° C in 1 per cent aqueous gentian violet. Charged negatively in solutions of hydrogen ion concentration up to about pH 8. Isoelectric point, pH 7.2 to 7.6. Inactivated by incubation *in vitro* at pH 6 with synthetic vitamin C (ascorbic acid).

Literature: Anderson, *Science*, 50, 1939, 497; *Am. Jour. Path.*, 46, 1910, 137-156; *Andervont, Jour. Inf. Dis.*, 44, 1929, 381-393; 45, 1929, 366-383, 49, 1931, 507-529; *Andrewes, Jour. Path. and Bact.*, 33, 1910, 301-312; *Bissett et al., Compt. rend. Acad. Sci., Paris*, 200, 1935, 1882-1884; *Bechhold and Schlesinger, Ztschr.*

weeks in 50 per cent glycerine and 16 months dried when frozen, and stored on ice.

Literature: Andrewes, *Brit. Jour. Exp. Path.*, 10, 1929, 188-190, 273-280; *Jour. Path. and Bact.*, 33, 1930, 301-312; 50, 1940, 227-234; Rivers and Stewart, *Jour. Exp. Med.*, 48, 1928, 603-613; Rivers and Tillett, *ibid.*, 39, 1924, 777-802; 40, 1924, 281-287; Topacio and Hyde, *Am. Jour. Hyg.*, 16, 1932, 99-124.

5. *Scelus ulceris spec. nov.* From Latin *ulcus*, sore spot.

Common name. Ovine balano-posthitis virus.

Host: *BOVIDAE*—*Ovis aries* L., sheep.

Geographical distribution: United States, Australia.

Induced disease: In sheep, ulceration with scab production: lesions most severe on prepuce and vulva; in the male, the penis may be involved, usually only with mild inflammation, but if accompanied by paraphimosis there may be extensive ulceration and heavy scab formation.

Transmission: Venereally. Experimentally, by inoculation of prepuce.

Filterability. Passes Berkefeld N and W filters, a 7 lb Mandler candle, and a 3½ per cent collodion membrane.

Literature Tunnick and Matisbeck, *Science*, 94, 1941, 283-284.

6. *Scelus marmorans spec. nov.* From Latin *marmorare*, to marble, in reference to mottling of spleen and liver in host.

Common name. Ectromelia virus.

Hosts: *MURIDAE*—*Mus musculus* L., white mouse. Experimentally, also *MURIDAE*—*Rattus norvegicus* (Berkenhout), rat (infection inapparent). Also, *PHASIANIDAE*—*Gallus gallus* (L.), chick embryo (12-day-old White Leghorn chick embryo at 36 to 37° C; less satisfactory results at higher temperatures of incubation or in embryos in spring eggs). Derived strains of this virus infect rabbit and guinea pig, not susceptible to original virus from mouse.

Geographical distribution: England.

Induced disease: In white mouse, spleen mottled, liver edges translucent, peritoneal fluid increased in amount; loss of weight; later, cutaneous lesions on foot or elsewhere; affected foot swells, becomes moist, scabbed, then recovers or dries up and separates from the skin at limit of original swelling; in acute disease, death without gross lesions, or, at autopsy, gut dark red, liver dirty gray, soft, bloodless, sometimes mottled, spleen necrotic; inclusion bodies most numerous in lesions of the skin, round or oval, 4 to 13 microns long, without internal differentiation; very young mice probably become infected without developing apparent disease and remain carriers for some time. In rat, inapparent infection; after initial increase of virus, circulating antibodies appear and immunity to reinfection is established.

Transmission: In mouse, by contact. In rat, experimentally, by intranasal inoculation.

Serological relationships: Neutralizing antibodies occur in convalescent mouse serum. Immune sera from the guinea pig specifically agglutinate elementary bodies obtained from infected skin of the white mouse.

Immunological relationships: Recovered mice are solidly immune to many lethal doses.

Thermal inactivation At 55° C in 30, not in 10, minutes.

Filterability. In broth, passes Mandler, Pasteur-Chamberland L<sub>2</sub>, and Berkefeld N filters.

Other properties: Survives drying 6 months, freezing (−10° C) 2 months, 50 per cent glycerine 5 months at least. Resists 1 per cent phenol 20, not 40, days. Size, estimated by filtration, 100 to 150

O. Bang, *Acta path. et microbiol. Scand., Suppl., 11, 1932, 180-182*; Carini and Maciel, *Bull. Soc. Path. exot., 5, 1912, 576-578*; Folger, *Acta path. et microbiol. 3. *Scelus beta spec. nov.* From *beta*, second letter of Greek alphabet, in reference to common name.

Common name B virus.

Hosts *HOMINIDAE*—*Homo sapiens* L., man. *CERCOPITHECIDAE*—*Macaca mulatta* (Zimmermann), rhesus monkey. Experimentally, also *LEPORIDAE*—*Oryctolagus cuniculus* (L.), rabbit. *CAVIIDAE*—*Cavia porcellus* (L.), guinea pig.

Geographical distribution: United States (from captive monkeys and man).

Induced disease. In man, local and relatively insignificant lesion on bitten part, later flaccid paralysis of legs, urinary retention, ascending paralysis, and death by respiratory failure. In *Macaca mulatta* experimentally by intracutaneous injection, hemorrhagic or vesiculo pustular lesions without later involvement of central nervous system but with subsequent acquired immunity. Acidophilic intranuclear inclusions in lesions.

Transmission. To man, by bite of monkey. To monkey, experimentally, by injection.

Literature. Burnet et al., *Austral. Jour. Exp. Biol. and Med. Sci., 17, 1939, 35-40, 41-51*; Sabin, *Brit. Jour. Exp. Path., 15, 1934, 218-268, 268-279, 321-331*; Sabin and

Hurst, *ibid., 16, 1935, 133-148*; Sabin and Wright, *Jour. Exp. Med., 59, 1931, 115-136*.

4. *Scelus tertium spec. nov.* From Latin *tertius*, third.

Common name: Virus III of rabbits.

Host *LEPORIDAE*—*Oryctolagus cuniculus* (L.), domestic rabbit.

Insusceptible species. No obvious disease in inoculated guinea pig, white mouse, monkey (*Macaca mulatta* Zimmermann), rat, or man, hence the assumption that these are naturally immune, but they may be merely tolerant or kleridase.

Geographical distribution: United States (apparently spontaneous in some individuals of the laboratory rabbit).

Induced disease. In domestic rabbit, experimentally, after incubation period of 4 to 6 days, failure to eat, loss of weight, occasionally diarrhea and temperatures of 101 to 107° F; small, superficial, red spots and papules on skin at site of inoculation, local infiltration of tissues with endothelial leucocytes, swelling of involved epithelial cells; nuclear inclusions present in endothelial leucocytes and some other cells; disease not fatal; virus in circulating blood only during early stages, recovery in a few days without scar formation but with development of specific immunity. The course of the natural disease, presumed to occur in rabbits, is still unknown.

Transmission. Experimentally, by injection of filtrates from diseased tissues, on several occasions also from blood or tissues of apparently normal rabbits.

Serological relationships. Specific neutralizing substances occur in the serum of recovered rabbits.

Immunological relationships. Specific immunity but no cross reactions with vaccinia or herpes viruses.

Thermal inactivation. In 10 minutes at 55° C, but not in 30 minutes at 45° C.

Filterability. Passes Berkefeld V and N filters, passes L<sub>1</sub> filter candle.

Other properties: Viable at least 6

*in vacuo*, at least a week at  $-4$  to  $0^{\circ}$  C. Readily destroyed by 1 to 2 per cent sodium hydrate or above pH 11. Soon inactivated near pH 6.0, but moderately stable at pH 2.0 to 3.0; optimum condition for storage at pH 7.5 to 7.7 in absence of air; return from 3.0 to 7.5 inactivates, however.

Literature: Elford and Galloway, Brit. Jour. Exp. Path., 18, 1937, 155-161; Galloway and Elford, *ibid.*, 14, 1933, 400-408, 16, 1935, 588-613; 17, 1936, 187-204; Galloway and Schlesinger, Jour. Hyg., 57, 1937, 463-470; Hare, Jour. Path. and Bact., 55, 1932, 291-293; Loeffler and Froesch, Cent. f. Bakt., I Abt., 23, 1898, 371-391, Matte and Sanz, Bull. Soc. Path. 2. *Hostis equinus spec. nov.* From Latin *equinus*, pertaining to horses.

Common names: Vesicular-stomatitis virus, equine vesicular stomatitis virus.

Hosts. Horse, domestic cattle. Experimentally, also guinea pig, swine, white mouse, rabbit (relatively resistant), chick embryo; *Macaca mulatta* (Zimmermann), rhesus monkey, *M. irus*, cynomolgus monkey.

Insusceptible species: Chicken (except embryo).

Geographical distribution: United States (Indiana, New Jersey).

Induced disease. In horse, resembles foot-and-mouth disease of cattle; reddened patches on buccal mucosa, moderate fever, salivation, followed by appearance of vesicles, especially on tongue, filled with clear or yellowish fluid; vesicles often coalesce and soon rupture leaving an eroded surface which heals soon in the absence of complications.

Experimentally, in chorioallantois of developing chick embryo, primary lesions involve moderate ectodermal proliferation, degeneration, necrosis; mesodermal inflammation; slight endodermal proliferation.

Serological relationships: Strains isolated in different localities give antisera capable of neutralizing heterologous isolates of virus, but homologous antisera neutralize in higher dilutions than do heterologous antisera.

Immunological relationships: No cross immunity with respect to equine encephalomyelitis virus.

Filterability: Passes Seitz filter.

Other properties: May be separated from mixtures with foot-and-mouth disease virus by propagation on chorioallantoic membrane of chick embryo, which will not support increase of the latter virus. Inactivated by 1:50,000 methylene blue in 2 mm layer 13 cm from 300 candle-power lamp in 60 minutes but not in 20 minutes. Particle estimated on the basis of filtration data to be 70 to 100 millimicrons in diameter; 60 millimicrons in diameter by centrifugation. Not destroyed by acidifying to pH 3 and returning to pH 7.5 (difference from foot-and-mouth disease virus).

Literature: Burnet and Galloway, Brit. Jour. Exp. Path., 15, 1934, 105-113; Cox and Olitsky, Proc. Soc. Exp. Biol. and Med., 50, 1933, 633-651; Cox et al., *ibid.*, 50, 1933, 896-898; Elford and Galloway, Brit. Jour. Exp. Path., 18, 1937, 155-161; Galloway and Elford, *ibid.*, 14, 1933, 400-408, 16, 1935, 588-613; Mohler, Jour. Am. Vet. Med. Assoc., 52, 1918, 410-422; Olitsky et al., Jour. Exp. Med., 59, 1934, 159-171; Pyl, Ztschr. f. physiol. Chemie, 226, 1934, 18-23; Sabin and Olitsky, *ibid.*, 66, 1937, 15-31, 35-57; 67, 1933, 201-228, 229-249; Syverton et al., Science, 78, 1933, 216-217.

7. *Scelus bovinum* spec. nov. From Latin *bovinus*, of ox, bull, or cow.

Common name: Erosive-stomatitis virus.

Host BOVIDAE—*Bos taurus* L., domestic cattle. Experimentally, also chorioallantoic membrane of developing hen's egg.

Insusceptible species. CAVIIDAE—*Cavia porcellus* (L.), guinea pig. (In rats, rabbits, mice, sheep, no reaction has been noted after inoculation.)

Geographical distribution: South Africa (Natal); perhaps Ireland (Armagh-disease virus).

Induced disease In young domestic

cattle, lesions on tongue, dental pad, and lips pearl-like at first, then breaking down to form superficial erosions, with white glistening base and red border. Lesions may coalesce to form large, ragged, eroded areas, healing uneventfully with scar formation. No foot lesions; no excessive salivation, no "hotness" of mouth; no systemic disturbances.

Transmission. Spreads slowly, mainly to animals less than three years old, probably by contact. Experimentally, by injection into dental pads, lips, or tongue. Filterability. Passes Gradocol membrane of about 400 millimicron average pore diameter.

Other properties. Viable after at least 11 days at room temperature, 21 days at refrigerator temperature, 6 weeks frozen and dried in horse-serum saline.

Literature: Mason and Neitz, Onderstepoort Jour. Vet. Sci. and Anim. Indust., 18, 1940, 159-173.

#### Genus IV. *Hostis* gen. nov.

Viruses of the Foot-and-Mouth Disease Group, inducing diseases mainly characterized by vesicular lesions. Generic name from Latin *hostis*, enemy or stranger.

The type species is *Hostis pecoris* spec. nov.

#### Key to the species of genus *Hostis*.

I. Infecting cattle and other animals with cloven hoofs; horse immune or highly resistant.

II Infecting horse readily

1. *Hostis pecoris*.

2. *Hostis equinus*.

1. *Hostis pecoris* spec. nov. From Latin *pecus*, cattle.

Common names Foot-and-mouth disease virus, Virus der Maul- und Klauen-senche.

Hosts Cow, pig, sheep, goat, reindeer, bison. Experimentally, also guinea pig, rabbit, rat.

Insusceptible species Chick embryo (chorioallantois), horse (immune or very resistant).

Induced disease In cow, after incubation period of 2 to 4 days or more, fever, vesicular lesions on tongue, lips, gums, hard palate and feet, non rupturing, salivation, lameness, generally recovery

Transmission Spread rapid, source of infection often obscure, saliva is infective before lesions become obvious.

Thermal inactivation At 70° C, not at 60° C, in 15 minutes.

Filterability Passes Seitz, Berkefeld V and N, and Chamberland L<sub>45</sub> filters.

Strains Three strains, A, O and C, are immunologically distinct from each other.

Other properties Particle calculated to be about 20 millimicrons in diameter by centrifugation data, 8 to 12 millimicrons in diameter by filtration, may be separated from mixtures with the larger equine vesicular stomatitis virus by differential filtration. Viable after drying

51, 1905, 1598-1599; Lipschütz, Arch. Dermat. u. Syph., 107, 1911, 387-396; in Kollo, Kraus and Uhlenhuth, Handbuch der Pathogenen Mikroorganismen, 8, 1930, 1031-1040; Van Rooyen, Jour. Path. and Bact., 46, 1938, 425-436; 49, 1939, 345-349; Wile and Kingery, Jour. Cutan. Dis., 37, 1919, 431-446.

3. *Mollitor bovis spec. nov.* From Latin *bos*, cow.

Common name: Cattle-wart virus.

Host: *BOVIDAE*—*Bos taurus* L., domestic cattle.

Geographical distribution: United States.

Induced disease. In cattle, especially about head, neck, and shoulders in young animals, on udders in cows, affected skin thickened at first, then rough, nodular; warts sometimes become large and pendulous, adversely affecting growth of host; they sometimes become cauliflower-like tumors several inches in diameter; spontaneous regression is not infrequent. Hides from affected animals are reduced in value.

Transmission: Believed to be through injuries to skin when the injured part comes in contact with warty animals or with rubbing posts, chutes, fences, buildings, or other structures with which affected animals have come in contact previously. Experimentally, by skin inoculations, especially in animals under 1 year of age.

Filterability: Passes Berkefeld N filter.

Literature: Creech, Jour. Agr. Res., 39, 1929, 723-737, U. S. Dept. Agr., Leaflet 75, 1931, 1-4.

4. *Mollitor buccalis spec. nov.* From Latin *bucca*, cheek.

Common name: Canine oral-papillomatosis virus.

Host: *CANIDAE*—*Canis familiaris* L., dog

Insusceptible species: Cat, rabbit, guinea pig, rat, mouse, *Macaca mulatta* (Zimmermann), rhesus monkey.

Induced disease: In young dog, experimentally, about 1 month after inoculation of buccal membrane by scarification,

pale, smooth elevations, becoming gradually more conspicuous and roughened; finally a mass of closely packed papillae is formed. Regression with subsequent immunity is frequent; no scars are left on regression. Secondary warts often appear in other parts of the mouth 4 to 6 weeks after primary warts have first been observed.

Transmission: Experimentally by skin scarification.

Serological relationships: Not inhibited by antiserum effective against common-wart virus of man.

Thermal inactivation: At some temperature between 45 and 58° C in 1 hour.

Filterability: Passes Berkefeld N filter.

Other properties: Viable after freezing and drying, if stored dry in icebox, at least 63 days; in storage in equal parts of glycerine and 0.9 per cent NaCl solution at least 64 days.

Literature: DeMonbreun and Goodpasture, Am. Jour. Path., 8, 1932, 43-56; M'Fadyean and Hobday, Jour. Comp. Path. and Therap., 11, 1898, 341-344; Penberthy, *ibid.*, 11, 1898, 363-365.

5. *Mollitor tumoris spec. nov.* From Latin *tumor*, swelling.

Common names: Fowl-sarcoma virus, Rous chicken-sarcoma virus.

Hosts: *PHASIANIDAE*—*Gallus gallus* (L.), chicken. Experimentally, also pheasant (serial transfer difficult) and duck (by cell transfer only but filtrates from duck infect injected chicken).

Insusceptible species: Turkey, guinea fowl (both immune to filtrates but capable of supporting tumor line if alternated in a series with common fowl hosts); geese.

Induced disease: In hen, originally found in an adult, pure-bred hen of Barred Plymouth Rock variety. Experimentally transmitted, a circumscribed nodule soon becomes evident at site of implantation; later this becomes necrotic or cystic at its center; as growth enlarges, host becomes emaciated, cold, somnolent, and finally dies; discrete metastases are often found in lungs, heart, and liver. Parent cell of sarcoma is claimed to be

Genus V. *Molitor* gen. nov.

Viruses of the Wart-Disease Group, inducing diseases mainly characterized by tissue proliferation without vesicle or pustule formation. Generic name from Latin *molitor*, contriver.

The type species is *Molitor verrucae* spec. nov.

Key to the species of genus *Molitor*.

1 *Molitor verrucae* spec. nov. From Latin *verruca*, wart.

Common name: Common-wart virus.

Hosts: *HOMINIDAE*—*Homo sapiens* L., man. Perhaps also *BOVIDAE*—*Bos taurus* L., cow. *CANIDAE*—*Canis familiaris* L., dog.

Induced disease. Experimentally in man, incubation period long, 4 weeks to 6 or more months, initially acanthosis (overgrowth of prickle cell layer of epidermis) and flattening of the papillae, later, interpapillary hypertrophy, inflammation, and marked hyperkeratosis.

Transmission. By contact, in some cases, venereally. Experimentally, by skin scarification.

Filterability. Passes Berkefeld N filter.

Literature. Ciuffo, Giorn. ital. d. malattie veneree e d. pelle, 48, 1907, 12-17; Kingery, Jour. Am. Med. Assoc., 70, 1921, 410-412; Payne, Brit. Jour. Dermat., 3, 1891, 185-188; Schultz, Deutsch. med. Wchnschr., 34, 1908, 423; Serra, Giorn. ital. d. malattie veneree e d. pelle, 65, 1921, 1808-1814; Ullmann, Acta otolaryngologica, 6, 1923, 317-331; Wile and Kingery, Jour. Am. Med. Assoc., 73, 1919, 970-973.

2. *Molitor hominis* comb. nov. (*Strongyloplasma hominis* Lipschütz,

Arch. Dermat. u. Syph., 107, 1911, 395.) From Latin *homo*, man.

Common name: *Molluscum contagiosum* virus.

Host: *HOMINIDAE*—*Homo sapiens* L., man.

Geographical distribution. Perhaps essentially world wide.

Induced disease. In man, experimentally, prodromal period may be 14 to 50 days, lesions at first like pimples, becoming red, painful, swollen, developing into small tumors covered with stretched and shiny skin; lesions commonest on face, arms, buttocks, back, and sides, healing spontaneously. Inclusions within epithelial cells, known as molluscum bodies, measure 9 to 21 microns in diameter when approximately spherical, 21 to 27 microns in width and 30 to 37 microns in length when elongated, they contain elementary bodies about 0.3 micron in diameter. The outer envelope of the molluscum body is of carbohydrate.

Transmission. By contact. By fomites.

Filterability: Passes Chamberland L<sub>4</sub> and Berkefeld V filters.

Literature: Goodpasture and King, Am. Jour. Path., 3, 1927, 385-391; Goodpasture and Woodruff, ibid., 7, 1931, 1-6; Juliusberg, Deutsch. med. Wchnschr.,

Erleben, snowshoe hare; *L. californicus* Gray, jack rabbit; *Sylvilagus* sp., cottontail rabbit.

Geographical distribution: United States.

Induced disease: In rabbit, benign papillomas, having the form of small, discrete, gray-white, sessile or pedunculated nodules, usually multiple, on lower surface of tongue or, less frequently, on gums or floor of mouth.

Transmission: Perhaps by mother to suckling young, with a latent period before onset of disease. Not highly contagious, if contagious at all, in old animals. Experimentally by puncture of tissues in the presence of virus.

Immunological relationships: Specific immunity develops as a result of disease, but no cross immunity with respect to rabbit-papilloma virus, which differs also in failing to act on oral mucosa.

Filterability: Passes Berkefeld V and N filters.

Literature: Parsons and Kidd, Jour. Exp. Med., 77, 1943, 223-250.

7. Molitor *sylvilagi* spec. nov. From New Latin *Sylvilagus*, generic name of cottontail rabbit.

Common names: Rabbit papilloma or papillomatosis virus, rabbit wart virus.

Hosts: *LEPORIDAE*—*Sylvilagus* sp., cottontail rabbit. Experimentally, also *LEPORIDAE*—*Oryctolagus cuniculus* (L.), domestic rabbit.

Geographical distribution: United States.

Induced disease: In cottontail rabbit, at first minute elevations along lines of scarification; later solid masses of wrinkled keratinized tissue, 3 to 4 millimeters in thickness, eventually cornified warts, striated perpendicularly at top, fleshy at base, 1 to 1.5 cm in height; regression rare, natural papillomas become malignant occasionally. In domestic rabbit, experimentally, blood antibody remains low but virus is always masked, preventing serial passage, discrete lesions on skin permit quantitative tests, tarring causes

localization of virus from blood stream; papillomas give rise to malignant acanthomatous tumors by graded continuous alteration; metastasis frequent; transplantation to new hosts successful in series; antibody specific for the virus is formed continuously in the transplanted growths although virus is not directly demonstrable by subinoculation from them; malignant growths appear more promptly and frequently where epidermis has been tarred long; virus appears specific for epithelium of skin; growths disappear if treated with X-rays, 3600 r at one time or fractionally; 60 per cent are cured with 3000 r, but 2000 r ineffective.

Transmission: Experimentally, by scarification of skin. Abnormal susceptibility to infection is noted in rabbit skin treated with 0.3 per cent methylcholanthrene in benzene or equal parts of turpentine and acetone.

Serological relationships: Specific neutralization, reversible on dilution. Complement fixation specific, with virus particle as antigen; no cross reaction with antisera for vaccinia, herpes, fibroma, or myxoma viruses. Precipitates occur in properly balanced mixtures of virus and specific antiserum; virus and antibody in both free and neutralized states are present in both soluble and insoluble phases of these suspensions.

Immunological relationships: Intraperitoneal injections immunize specifically. Rabbits immunized to fibroma and myxoma viruses are susceptible to rabbit papilloma virus.

Thermal inactivation: At 70° C, not at 65 to 67° C, in 30 minutes; in 0.9 per cent sodium chloride solution at 65 to 66° C, time not stated.

Filterability: Passes Berkefeld V, N, and W filters; particle size calculated as 23 to 35 millimicrons by filtration as compared with 32 to 50 millimicrons by centrifugation and 41.0 millimicrons by measurement of electron micrographs, which show the particle to be approximately spherical in shape.

the normal histiocyte, but virus in the affected fowl is not confined to the sarcoma, being widespread in the body in spleen, liver, muscle, brain, etc. In the chick embryo, serial passage is feasible on the egg membrane, in which focal lesions involve only ectodermal tissue.

**Transmission.** By injection of affected fowl cells or filtrates. Certain transmissible tar-induced sarcomas, not infecting by filtrates, nevertheless induce the formation of antibodies capable of neutralizing this virus. An inhibitor of the virus extracted from tumors appears to be a protein, inactivated at 65° C, but not at 55° C, in 30 minutes and destroyed by trypsin in 3 to 5 hours at pH 8. Oleic acid also may act as an inhibitor. No spontaneous transmission in chickens kept together.

**Serological relationships:** Particles sedimented by centrifugal force 20,000 to 30,000 times gravity are specifically agglutinated by sera of fowls bearing corresponding tumor. At least one antigen in tumors of hen and duck not in healthy birds, this one fixes complement and gives cross reactions with Rous, Mill Hill 2, Fujinami, and RFD2 tumors. Virus injected into goats produces two antibodies but only one if previously heated, the antibody to the heat-stable constituent requires complement to neutralize virus, the only antibody produced in ducks does not require complement to neutralize.

**Thermal inactivation.** At or below 51° C in 20 minutes.

**Filterability.** Passes Berkefeld V and no 5 (medium) filters.

**Other properties.** Particle size estimated as about 100 millimicrons (but some say 50 or even 15 millimicrons) in diameter by filtration through graded membranes, about 70 millimicrons (molecular weight 140,000,000) by ultracentrifugation. Contains 8.5 to 9.0 per cent nitrogen, 1.5 per cent phosphorus. Protein tests positive. Feulgen reaction for thymonucleic acid absent, 10 to 15 per cent of the protein may be nucleic

acid, probably of ribose type. Pentose present. Virus believed to be of globulin nature or attached to globulin particles (Lewis and Mendelsohn, *Am. Jour. Hyg.*, 12, 1930, 686-689). Viable indefinitely in dried spleen as in dried sarcoma tissues.

**Strains:** Several strains have been studied in addition to the original Rous sarcoma no. 1 strain; immunological relationships have been shown between the original strain, the des Ligneris sarcoma strain, the Fujinami sarcoma strain, the fibrosarcoma MH1 and endothelioma MH2 strains, other isolates also have shown serological interrelationships.

**Literature:** Amies, *Jour. Path. and Bact.*, 44, 1937, 141-166; Amies et al., *Am. Jour. Cancer*, 35, 1939, 72-79; Andrewes, *Jour. Med.*, 13, 1911, 397-411.

6. *Molitor gingivalis spec. nov.* From Latin *gingiva*, gum.

**Common name:** Rabbit oral-papillomatous virus.

**Hosts.** LEPORIDAE—*Oryctolagus cuniculus* (L.), domestic rabbit. Experimentally, also *Lepus americanus*

Rods: 1.0 by 1.0 to 3.0 microns, occurring singly and in pairs. Motile with one to five polar flagella. Gram-negative.

Gelatin colonies: Circular, white with buff center, convex, smooth, undulate.

Gelatin stab: No liquefaction.

Agar colonies: Circular or amoeboid, white to buff, flat to convex, smooth, entire.

Agar slant: Filiform, pale buff, raised, smooth, undulate.

Broth: Turbid.

Nitrites not produced from nitrates.

Starch not hydrolyzed.

No acid in carbohydrate media.

Attack phenol and *m*-cresol.

Aerobic, facultative.

Optimum temperature 30 to 35°C.

Habitat: Soil.

#### 42. *Pseudomonas rugosa* (Wright)

Chester. (*Bacillus rugosus* Wright, *Memoirs Nat. Acad. Sci.*, 7, 1895, 438; not *Bacillus rugosus* Henrici, *Arb. Bakt. Inst. Tech. Hochsch. Karlsruhe*, 1, 1894, 28; not *Bacillus rugosus* Chester, *Determinative Bacteriology*, 1901, 220, Chester, *Determinative Bacteriology*, 1901, 323.) From Latin, *rugosus*, wrinkled.

Small rods, with rounded ends, occurring singly, in pairs and in chains. Motile, possessing one to four polar flagella. Gram-negative.

Gelatin colonies: Grayish, translucent, slightly raised, irregular, sinuous, radiately erose to entire.

Gelatin stab: Dense, grayish-green, limited, wrinkled, reticulate surface growth. No liquefaction.

Agar slant: Grayish-white, limited, slightly wrinkled, translucent.

Broth: Turbid, with grayish pellicle and sediment.

Litmus milk: Acid, coagulated.

Potato: Moist, glistening, brown.

Indole is formed.

Nitrites not produced from nitrates.

Aerobic.

Optimum temperature 30°C.

Habitat: Water.

43. *Pseudomonas desmolyticum* Gray and Thornton. (Gray and Thornton, *Cent. f. Bakt.*, II Abt., 73, 1928, 90; *Achromobacter desmolyticum* Bergey et al., *Manual*, 3rd ed., 1930, 217.) From Greek *desmos*, bond, band; *lytikos*, able to dissolve.

Rods: 0.7 to 0.8 by 2.0 to 3.0 microns, occurring singly and in pairs. Motile, with one to five polar flagella. Gram-negative.

Gelatin colonies: Circular, gray to buff, raised or umbonate. Smooth, glistening, entire.

Gelatin stab: No liquefaction.

Agar colonies: Circular or amoeboid, whitish, flat or convex, smooth, translucent to opaque, entire.

Agar slant: Filiform, pale buff, raised, smooth, undulate.

Broth: Turbid.

Nitrites produced from nitrates.

Starch not hydrolyzed.

Acid from glucose.

Attack phenol and naphthalene.

Aerobic, facultative.

Optimum temperature 25°C.

Habitat: Soil.

44. *Pseudomonas rathonis* Gray and Thornton. (Gray and Thornton, *Cent. f. Bakt.*, II Abt., 73, 1928, 90; *Achromobacter rathonis* Bergey et al., *Manual*, 3rd ed., 1930, 216.) From M. L. of Ratho Park (Edinburgh).

Small rods: 0.5 to 1.0 by 1.0 to 3.0 microns. Motile, with polar flagella. Gram-negative.

Gelatin colonies: Circular, white, raised, smooth, glistening, undulate.

Gelatin stab: No liquefaction.

Agar colonies: Circular, buff, flat, smooth, glistening, entire.

Agar slant: Filiform, pale buff, convex, smooth, glistening, undulate.

Broth: Turbid, with pellicle.

Nitrites produced from nitrates.

Starch hydrolyzed.

Acid from glucose and glycerol.

Other properties: Infectious particle has sedimentation constant  $S_{20} = ca. 250 \times 10^{-13}$  cm per sec. per dyne; usually there is a secondary boundary at about  $375 \times 10^{-12}$ . Isoelectric point between pH 4.8 and 5.1. Maximum absorption at about 2750 Å. Contains thymus nucleic acid about 6.8 to 8.7 per cent; maximum absorption of nucleic acid at about 2630 Å.

Literature: Beard et al., Jour. Inf. Dis., 65, 1939, 43-52, 69, 1941, 173-192, Bryan and Beard, *ibid.*, 65, 1939, 306-321, Friedewald, Jour. Exp. Med., 75, 1912, 197-220, Hoyle, Jour. Path. and Bact., 50, 1940, 169-170, Kidd, Jour. Exp. 8 *Mollitor myxomae* (Aragão) comb. nov. (*Chlamydozoon myxomae* Araújo, Brazil Med., 25, 1911, 471, name later abandoned by its original author in favor of *Strongyloplasma myxomae* Araújo, Mem. Inst. Oswaldo Cruz, 20, 1927, 231 and 243. The name *Sonarellia cuniculi* Lipschütz, Wien klin. Wochenschr., 40, 1927, 1103, was based on the supposed causative organism, defined as varying in size between the size of chlamydozoa and of large cocci; it is not clear whether the structures observed and named were virus particles or not.) From New Latin *myxoma*, a kind of soft tumor, from nature of induced lesion.

Common names: Myxoma virus, virus myxomatosum.

Hosts: *LEPORIDAE*—*Oryctolagus cuniculus* (L.), domestic rabbit. Experimentally, also *Sylvilagus* sp., cottontail rabbit; jack rabbit (once in many trials), *Lepus brasiliensis* (resistant and rarely infected). Also chick embryo and duck embryo.

Insusceptible species: *Lepus californicus* Gray, black-tailed jack rabbit; *L. americanus* Erxleben, varying hare; *Sylvilagus transitionalis* Bangs, cottontail; horse, sheep, goat, cattle, dog (but one reported infected), guinea pig, rat, mouse, fowl, pigeon, duck, cat, hamster, monkey; man (but some conjunctival pain and swelling).

Geographical distribution: South America (Brazil, Uruguay, Argentina), United States (California).

Induced disease: In domestic rabbit, a disease (myxomatosis *cuniculi*) almost always fatal at ordinary room temperatures but not at 36 to 42° C, lesions fewer and regressing after 6 to 8 days at these higher temperatures in most animals. At ordinary temperatures, nodules (edematous tumors) in skin near eyes, nose, mouth, ears, and genitalia; edema of eyelids; conjunctivitis with purulent discharge if skin around eyes is involved. Later marked dyspnea, stertorous breathing, cyanosis, asphyxia. Animals usually die within 1 to 2 weeks of infection. Virus enters bloodstream and invades nervous system at random through walls of blood vessels. Discharges from nose, eyes, and the serous exudates from affected tissues are infectious, urine and feces are not. There are cytoplasmic inclusions in affected epidermal cells. In chick embryo, experimentally, intense inflammation, eventual impairment of circulation and necrosis locally, growth best if embryo is grown at 33 to 35° C and chilled to 25° C for 12 to 18 hours before or after inoculation, lesions being linear and associated with capillaries in ectoderm; virus infects and is recoverable from embryo and depresses hatch.

Transmission: By contact with diseased rabbits or cages recently occupied

by them. Through air for a few inches. Rarely by feeding. Experimentally, by rubbing conjunctiva with a bit of infected tissue or with a platinum loop contaminated from diseased conjunctiva; has been recovered from flies. By injection. By flea, *Ctenopsylla felis* (*PULICIDAE*), rarely.

**Serological relationships:** An attack of the disease induces the formation of neutralizing antibodies. Cross neutralization by antisera to myxoma and fibroma strains. Complement is fixed with myxoma virus as test antigen in the presence of antisera to myxoma or fibroma strains. Serum of rabbit inoculated with a soluble antigen, a heat-labile protein with isoelectric point near pH 4.5, agglutinates myxoma elementary bodies. A second soluble antigen, also heat labile, appears distinct, inhibiting its own antibody even after inactivation of its precipitating power by exposure at 56° C.

**Immunological relationships:** Myxoma-recovered domestic rabbits become immune to reinfection, fibroma-strain-recovered animals, although partially immunized, still support myxoma-strain virus introduced into the testicle. Heat-inactivated virus (60° C for 30 minutes) tends to immunize if given intradermally, there is then an allergic local response, less severe generalized disease, delayed death or recovery. If fibroma virus precedes myxoma virus by 48 to 96 hours, there is marked protection.

**Thermal inactivation:** At 55° C in 10 minutes, at 50° C in 1 hour. A substance thermostable for 30 minutes at 60 to 75° C, but not at 90° C, is itself unable to produce myxomatous changes after the heat treatment but may do so in combination with fibroma virus, and transmissible myxoma virus is then reconstituted. Although it is supposed by some that this indicates the transformation of fibroma-strain virus into myxoma-strain virus, the possibility that heat-modified myxoma-strain virus is reactivated has not been eliminated.

**Filterability:** Passes Berkefeld V and N filters; not Chamberland L<sub>4</sub> or L<sub>7</sub> filters.

**Other properties:** Inactivated above pH 12.0 and below pH 4.0. Withstands drying. Viable at least 3 months at 8 to 10° C.

Strains and substrains: A strain from cottontail rabbits (*Sylvilagus* sp.), differing from typical myxoma virus, has been studied extensively under the name fibroma virus. This strain in turn is recognized as consisting of variants and has been investigated as typical (OA) and inflammatory (IA) substrains, antigenically alike but the latter tending to generalize in domestic rabbits. Fibroma virus is not lethal in domestic rabbits as the type strain almost always is; it appears to lack some antigenic constituents, inducing the formation of agglutinins that give cross reactions with the type but of neutralizing and complement-fixing antibodies that do not. The fibroma strain does not generally appear in the blood stream, as myxoma virus does, and is not contagious, at least it

does not spread spontaneously among domestic rabbits as the myxoma strain does; the manner of its spread in wild rabbits in nature is not known. Its particle size has been calculated as 126 to 141 millimicrons by centrifugation, 125 to 175 millimicrons by filtration. (Ahlström, Jour. Path. and Bact., 46, 1938, 461-472; Andrewes, Jour. Exp. ## FAMILY III. ERRONACEAE FAM. NOV.

Viruses of the Encephalitis Group, inducing diseases mainly characterized by effects on nerve tissues.

## Key to the genera of family Erronaceae.

- I. Viruses of the Typical Encephalitis Group.  
Genus I. *Erro*, p. 1248.
- II. Viruses of the Poliomyelitis Group  
Genus II. *Legio*, p. 1257.
- III. Viruses of the Rabies Group.  
Genus III. *Formido*, p. 1263.

Genus I. *Erro* gen. nov.

Viruses of the Typical Encephalitis Group, inducing diseases mainly characterized by injuries to cells of the brain. Vectors of some known to be ticks; dipterous insects also transmit. Generic name from Latin *erro*, a vagrant.

The type species is *Erro scoticus* spec. nov.

Key to the species of genus *Erro*.

- I. Affecting sheep principally, but also man.  
1. *Erro scoticus*.
- II. Affecting man principally.  
2. *Erro silvestris*  
3. *Erro incognitus*.  
4. *Erro japonicus*.  
5. *Erro nili*.  
6. *Erro scelestus*.
- III. Affecting horse principally, but also man.  
7. *Erro equinus*.
- IV. Affecting horse, cow, sheep.  
8. *Erro bornensis*.

1. *Erro scoticus* spec. nov. From Latin *Scoticus*, Scottish.

Common name Louping-ill virus.

Hosts: BOVIDAE—*Ovis aries* L., sheep. HOMINIDAE—*Homo sapiens* L., man. Experimentally, also mouse, rat (subclinical infection), chick embryo (discrete primary lesions on chorioallantoic membrane), *Macacus rhesus*, horse, cow, pig.

Insusceptible species: Guinea pig, rabbit.

Geographical distribution: Scotland, northern England.

Induced disease: In sheep, encephalitis characterized by dullness followed by incoordination of movement, frequently with tremors chiefly of the head, saliva-

tion, champing of jaws; prostration, coma, death. In man, encephalitis with prompt and complete recovery accompanied by formation of specific neutralizing antibodies. In mouse, experimentally, diffuse encephalomyelitis with mild meningeal involvement, following intracerebral inoculation, fine rhythmical tremor involving neck, nose, and ears, unsteadiness, muscle spasms, respiratory distress, sometimes clonic and rarely tonic convulsions; hind limb paralysis, dribbling of urine, cessation of spontaneous limb movements, death; in mouse inoculated intraperitoneally, virus usually enters central nervous system by way of the olfactory mucosa and olfactory bulb, occasionally by trauma at points of

damage; in mouse inoculated intranasally, virus enters blood and reaches the olfactory bulb where it multiplies to a high concentration before infecting the remainder of the brain and the rest of the nervous system, tends to disappear from the blood after sickness begins but persists in the brain until death from encephalitis. In chick embryo, after inoculation of chorioallantoic membrane, edema and opacity spreading from site of inoculation on membrane of 10-day embryo, in 12-day eggs, discrete primary lesions, sometimes with secondary lesions surrounding them on the inoculated membrane, embryo dies in about 6 days, after showing jaundice, edema, mottling of the liver with necrosis; virus regularly in blood. In monkey, *Macacus rhesus*, progressive cerebellar ataxia; encephalomyelitis with involvement and massive destruction of Purkinje cells in the cerebellum.

**Transmission:** By ticks, *Rhipicephalus appendiculatus* and *Ixodes ricinus* (IXODIDAE). In *Rhipicephalus appendiculatus*, the larva or nymph becomes infected, only a few individuals retain virus until the adult stage, virus does not pass through the egg. Non-viruliferous ticks do not acquire virus by feeding with infective ticks on immune animals. Experimentally, by intracerebral or intraperitoneal injection in mouse, by intranasal instillation in rat, mouse, and monkey.

**Serological relationships.** Complement fixation and neutralization tests show cross reactions with Russian spring-summer encephalitis virus, but immune serum against louping-ill virus is only partially effective in neutralizing the spring-summer encephalitis virus.

**Immunological relationships.** Mice are protected against louping-ill virus by vaccination with non-virulent spring-summer encephalitis virus but protection is less effective than for the homologous virus. No cross immunity with respect to Rift Valley fever virus or poliomyelitis virus in *Macacus rhesus*, but immunity

with respect to reinfection by louping-ill virus has been demonstrated.

**Thermal inactivation:** At 58° C in 10 minutes.

**Filterability:** Passes Berkefeld V, N, and W filters.

**Other properties:** Viable in broth filtrates after storage at 4° C and pH 7.6 to 8.5 for 70 days. Particle diameter, calculated from ultrafiltration data, 15 to 20 millimicrons.

**Literature:** Alexander and Neitz, *Vet. Jour.*, 60, 1933, 320-323; Onderstepoort *Jour. Vet. Sci. and Anim. Industr.*, 6, 1935, 15-33; Alston and Gibson, *Brit. Jour. Exp. Path.*, 12, 1931, 82-83; Burnet, *Jour. Path. and Bact.*, 42, 1936, 213-225; *Brit. Jour. Exp. Path.*, 17, 1936, 294-301; Burnet and Lush, *Austral. Jour. Exp. Biol. and Med. Sci.*, 16, 1938, 233-240; Casals and Webster, *Science*, 97, 1913, 246-248; *Jour. Exp. Med.*, 79, 1944, 45-63; Efford and Galloway, *Jour. Path. and Bact.*, 57, 1933, 381-392; Findlay, *Brit. Jour. Exp. Path.*, 13, 1932, 230-236; Fife and Webster, *Proc. Soc. Exp. Biol. and Med.*, 31, 1931, 695-698; Galloway and Perdrau, *Jour. Hyg.*, 35, 1935, 339-346; Hurst, *Jour. Comp. Path. and Therap.*, 44, 1931, 231-245; M'Fadyean, *Jour. Comp. Path. and Therap.*, 7, 1894, 207-210, 13, 1900, 145-154; Pool et al., *ibid.*, 43, 1930, 253-290; Rivers and Schwenker, *Jour. Exp. Med.*, 69, 1934, 609-655; Schwenker et al., *ibid.*, 67, 1933, 955-965.

2. *Erro silvestris* spec. nov. From Latin *silvestris*, of the forest, in reference to incidence of the induced disease almost exclusively in those who enter forest lands.

**Common names.** Spring-summer encephalitis virus, forest spring encephalitis virus.

**Hosts.** Man; probably cattle, horse; *Eutamias asiaticus orientalis*, *Eutamias rufocanus arsenjersi*. Experimentally, also white mouse, *Macacus rhesus*, birds, goat, sheep, *Microtus musknot pelliceus* Thom., *Cricetus furunculus*.

Geographical distribution: Union of Soviet Socialist Republics.

Induced disease: In man, acute non-suppurative encephalitis, abrupt onset, steep rise of temperature to 38 to 40° C, severe headache, giddiness, and vomiting; pareses and paralyzes of upper or lower limbs or muscles of neck and back; residual atrophic paralyzes common; mortality among cases, 30 per cent; 80 per cent of all cases occur in May and June.

Transmission: By tick, *Ixodes persulcatus* (IXODIDAE); the virus seems to hibernate in this species and has proved capable of passing through eggs to progeny. Experimentally, also by ticks *Dermacentor silvarum* and *Haemaphysalis concinna* (IXODIDAE).

Serological relationships: Virus-neutralizing antibodies, found without other evidence of disease in some men and in many cattle and horses, believed to indicate susceptibility of these hosts to latent infections. No cross neutralization with St. Louis encephalitis virus. Japanese summer encephalitis virus is in part antigenically related, but some antigenic constituents of this virus are missing in spring-summer encephalitis virus and vice versa.

Immunological relationships: Formolized virus immunizes specifically.

Filterability: Passes Berkefeld and Chamberland filter candles.

Literature: Smorodintseff, Arch. f. gesamt. Virusforsch., 1, 1940, 463-480; Soloviev, Acta Med. U. R. S. S., 1, 1938, 484-492 (Biol. Abst., 17, 1943, 1726, no. 18777).

3. *Erro incognitus spec. nov.* From Latin *incognitus*, unknown, in reference to mystery surrounding the nature and relationships of this virus, as evidenced by common name.

Common name: Australian X-disease virus.

Hosts. HOMINIDAE—*Homo sapiens* L., man. Experimentally, also sheep, horse, cow, rhesus monkey.

Geographical distribution: Australia.

Induced disease: In man, poliomyelitis, especially in children, occurring in late summer; mortality high; characterized by headache, body pains, drowsiness, weakness, then vomiting, fever, convulsions; paralysis of limbs, eye-muscles, or face rate; recovery rapid in non-fatal cases.

Literature: Kneebone, Austral. Jour. Exp. Biol. and Med. Sci., 3, 1926, 119-127; Perdrau, Jour. Path. and Bact., 42, 1936, 59-65.

4. *Erro japonicus spec. nov.* From New Latin *Japonia*, Japan.

Common name: Japanese B encephalitis virus.

Hosts: HOMINIDAE—*Homo sapiens* L., man. Experimentally, also young sheep, mouse, and *Macacus rhesus*.

Geographical distribution: Japan, Union of Soviet Socialist Republics.

Induced disease: In man, loss of appetite, drowsiness, nausea, then rapid rise of temperature, pains in joints and chest; restlessness followed by apathy, coma; death, usually before end of second week, or recovery, sometimes with persistence of evidences of damage done to the nervous system by the disease.

Serological relationships. Specific antiserum does not neutralize St. Louis encephalitis virus or louping-ill virus. Russian autumn-encephalitis virus induces the formation of antisera neutralizing Japanese B encephalitis virus. Russian spring-summer encephalitis virus contains some, but not all, antigens in common with this virus. Australian X-disease virus is distinct in neutralization tests.

Immunological relationships: Specific immunity as a result of earlier infection in mice; no cross protection with respect to St. Louis encephalitis virus. Vaccination with Japanese B encephalitis virus does not enhance resistance to West Nile encephalitis virus but only to the homologous virus.

Thermal inactivation: At 56° C in 30 minutes

Filterability - Passes Berkefeld N, W, Chamberland L<sub>2</sub>, L<sub>3</sub>, and Seitz EK filters, with ease

Literature. Kudo et al., Jour Immunol., 32, 1937, 129-135; Smorodintseff et al., Arch. f. gesamt. Virusforsch., 1, 1940, 550-559, Webster, Jour Exp Med, 67, 1938, 609-618

5. *Erro nili spec. nov.* From Latin *Nilus*, god of the Nile

Common name West Nile encephalitis virus

Hosts HOMINIDAE—*Homo sapiens* L., man (perhaps without inducing any definite disease) Experimentally, also rhesus monkey, mouse

Geographical distribution Africa (Uganda)

Induced disease In man, no details are known, virus was originally isolated from blood of a woman native of Uganda, at the time the temperature of the patient was 100.6° F but she denied illness, moreover, two laboratory workers developed neutralizing antibodies without recognizable clinical disease. In mouse, experimentally, after intracerebral inoculation, incubation period to 4 or 5 days, then hyperactivity and roughening of coat; later, weakness, hunched attitude, sometimes paralysis of hind quarters, usually coma before death. In rhesus monkey, experimentally, after intracerebral or intranasal inoculation, fever and encephalitis

Serological relationships No cross reactions in complement fixation tests between this and equine encephalitis virus, Japanese B encephalitis virus, St. Louis encephalitis virus, or lymphocytic choriomeningitis virus. Neutralization tests show some common antigens in West Nile encephalitis virus, Japanese B encephalitis virus and St. Louis encephalitis virus, antiserum to West Nile virus does not neutralize either of the others but antisera against St. Louis virus may neutralize West Nile virus and antisera

against Japanese B virus have some effectiveness in neutralizing both West Nile virus and St. Louis virus.

Immunological relationships: Vaccination with this virus does not enhance resistance to Japanese B or St. Louis encephalitis viruses but only resistance to the homologous virus.

Thermal inactivation. At 55° C, not at 50° C, in 30 minutes.

Filterability Passes Berkefeld V, N, and W filter candles readily; also passes Seitz EK asbestos pads and collodion membranes 79, not 62, millimicrons in average pore diameter.

Other properties Infective particle 21 to 31 millimicrons in diameter, as calculated from filtration experiments. Viable at least 2 weeks at 2 to 4° C. Viable after drying from the frozen state.

Literature Havana et al., Jour. Exp. Med., 77, 1913, 139-153, Smithburn, Jour. Immunol., 44, 1912, 25-31, Smithburn et al., Am Jour. Trop. Med., 30, 1910, 471-492.

6. *Erro scelestus spec. nov.* From Latin *scelestus*, infamous

Common name St. Louis encephalitis virus.

Hosts HOMINIDAE—*Homo sapiens* L., man A great number of mammals and birds in endemic areas may have antisera that neutralize the virus, indicating that they are probably natural hosts, among these are ANATIDAE—*Anas platyrhynchos* L., Mallard and Pekin ducks, *Anser anser* (L.), domestic geese BOVIDAE—*Bos taurus* L., cow, *Capra hircus* L., goat, *Ovis arica* L., sheep. CANIDAE—*Canis familiaris* L., dog COLUMBIDAE—*Columba livia*, domestic pigeon, *Zenaidura macroura*, western mourning dove. EQUIDAE—*Equus caballus* L., horse. FALCONIDAE—*Falco sparverius* L., sparrow hawk. LEPORIDAE—*Lepus californicus* Gray, jack rabbit, *Sylvilagus nuttalli*, cottontail rabbit. MELEAGRIDAE—*Meleagris gallopavo* L., turkey. MURIDAE—*Rattus norvegicus* (Berkenhout), brown

rat. **MUSCICAPIDAE**—*Turdus migratorius* L., robin. **PHASIANIDAE**—*Gallus gallus* (L.), chicken; *Lophortyx californica*, California quail. **PICIDAE**—*Asyndesmus lewis*, Lewis woodpecker; *Colaptes cafer* (Gm.), red-shafted flicker. **STRIGIDAE**—*Bubo virginianus* (Gm.), great horned owl. **SUIDAE**—*Sus scrofa* L., pig. Experimentally, white mouse (some substrains of the Swiss white mouse are genetically more readily infected than others); *Macacus rhesus*; pigeon (inapparent infection); chick embryo and to a limited extent the young hatched chick.

**Insusceptible species:** Laboratory rabbit, *Cebus* monkey, guinea pig, rat.

**Geographical distribution:** United States.

**Induced disease:** In man, during summer and fall, about 9 to 21 days after exposure, headache, high fever, rigidity of neck, tremors, encephalitis, usually with fever; some patients become drowsy, others sleepless or delirious; usual sequelae headaches, irritability, some loss of memory, and drowsiness; neutralizing antibodies maintained *in vivo* at least 2½ years after occurrence of disease. Experimentally, in susceptible strains of white mouse inoculated by intracerebral injection, after 3 to 4 days, coarse tremors, convulsions, prostration, death; perivascular accumulations of mononuclear leucocytes throughout brain, stem, cord, and pia, with destruction of pyramidal cells in the lobus piriformis and cornu Ammonis, subcutaneous and intraperitoneal injections immunize against subsequent infection by intracerebral inoculation, virus reaching only blood and spleen in the process of immunization unless an excessive dose is given, some substrains of the White Swiss mouse are relatively resistant to infection, requiring inoculation with about 1000 times the minimal infective dose for highly susceptible strains and when infected proving relatively poor sources of virus for subinoculation; highly susceptible substrains of the White Swiss mouse lack a single

major, dominant, genetic factor that is present in resistant substrains.

**Transmission.** By mosquito, *Culex tarsalis* Coquillett (**CULICIDAE**), probably extensively; this insect has been collected in nature carrying the virus. Experimentally, by larvae of American dog tick, *Dermacentor variabilis* (Say) (**IXODIDAE**); by mosquito, *Culex pipiens* Linn., var. *pallans* Coq. (**CULICIDAE**). To mice, by feeding on infected tissues.

**Serological relationships:** Human antisera may neutralize virus after clinical and subclinical attacks.

**Immunological relationships:** Specific intracerebral immunity after vaccination by subcutaneous or intraperitoneal injection in mice appears early (about 1 week after vaccination) and disappears before humoral antibody titer reaches its maximum.

**Thermal inactivation:** At 56° C in 30 minutes.

**Filterability:** Passes Berkefeld V and N filter candles and collodion membranes 66 millimicrons in average pore diameter.

**Other properties:** Storage in human brain tissue in glycerine inactivates this virus in about 32 days. Diameter of infective particle calculated from filtration data as about 20 to 33 millimicrons. In storage, rabbit and sheep sera act to some extent as preservatives. At 4° C, after drying *in vacuo* while frozen, viable in apparently undiminished titer for at least 17 months.

7. *Erro equinus spec. nov.* From Latin *equinus*, pertaining to horses.

Common name. Equine encephalitis virus.

Hosts. **EQUIDAE**—*Equus caballus* L., horse; *T.*, hybrid of the horse and *E. asinus* L., mule. **HOMINIDAE**—*Homo sapiens* L., man. **COLUMBIDAE**—*Columba livia*, domestic pigeon. **PHASIANIDAE**—ring-necked pheasant. **TETRAONIDAE**—*Tympanuchus cupido* L., var. *americanus* (Reichenbach), prairie chicken. Many additional species have been found to show neutralizing antisera at times and these are presumably natural hosts of the virus upon occasion, among them are: **ANATIDAE**—*Anas platyrhynchos* L., Mallard and Pekin ducks, *Anser anser* (L.), domestic goose. **BOVIDAE**—*Bos taurus* L., cow, *Capra hircus* L., goat, *Ovis aries* L., sheep. **CANIDAE**—*Canis familiaris* L., dog. **CHARADRIIDAE**—*Oxyechus vociferus* L., killdeer. **CRICETIDAE**—*Microtus montanus* (Peale), field mouse, *Peromyscus maniculatus* (Wagner), white footed mouse. **FALCONIDAE**—*Falco sparverius* L., sparrow hawk. **MELEAGRIDAE**—*Meleagris gallopavo* L., turkey.

**MURIDAE**—*Rattus rattus* L., black rat. **MUSCICAPIDAE**—*Turdus migratorius* L., robin. **MUSTELIDAE**—*Mustela frenata* Lichtenstein, weasel. **PHASIANIDAE**—*Gallus gallus* (L.), chicken; *Lophortyx californica*, California quail; *Phasianus colchicus* L., ring-necked pheasant. **PICIDAE**—*Colaptes cafer* (Gm.), red-shafted flicker. **STRIGIDAE**—*Bubo virginianus* (Gm.), great horned owl. **SUIDAE**—*Sus scrofa* L., pig. Experimentally, also chick embryo, goose embryo, pheasant embryo, robin embryo, pigeon embryo, turkey embryo, sparrow embryo, duck embryo, and guinea-fowl embryo; white mouse, guinea pig, rabbit, pigeon, white rat, calf, sheep, monkey, goat, dog, hen, turkey; *Zonotrichia leucophrys gambeli*, Gambel sparrow; *Passer domesticus* L., English sparrow; *Lophortyx californica*, quail; *Junco oreganus*, junco; *Toxostoma lecontei lecontei*, thrasher; *Citellus richardsonii* (Sabine), gopher or Richardson's ground squirrel; *Sigmodon hispidus* Say and Ord, cotton rat; *Dipodomys heermanni* Le Conte, kangaroo rat; *Reithrodontomys megalatus*, wild mouse; *Microtus montanus*, *M. californicus* and *M. mordax*, wild mice, *Peromyscus maniculatus* (Wagner), white footed mouse; *Neotoma fuscipes* Baird, wood rat; *Sylvilagus bachmani* (Waterhouse), brush rabbit; *S. auduboni* (Baird), cottontail rabbit; *Canis familiaris* L., dog (puppies); *Anser cinereus*, goose; *Anas boschas* L., duck; *Circus rufus* (Gm.), hawk; *Turdus merula* L., blackbird, *Ciconia ciconia* L., white stork, *Fulvus fulvus* Brisson, tawny vulture, *Marecula monax* (L.), woodchuck, *Microtus pennsylvanicus* (Ord.), field vole; *Speotyto cunicularia hypugna* (Bonaparte), western burrowing owl; *Molothrus ater* (Boddaert), cowbird; common quail or bob white.

In susceptible species: Frog (cat and opossum reported as "refractory").

Geographical distribution: United States, Canada, Argentina.

Induced disease: In horse, initial fever, then signs of fatigue, somnolence; occa-

sional excitability followed by incoordinated action of limbs, disturbed equilibrium, grinding of teeth, paresis and varied paralyses; frequently inability to swallow, paralysis of lips and bladder, amaurosis; case fatality about 50 per cent; recovery without sequelae in mild cases; death within 3 to 8 days in severe cases. In man (children particularly vulnerable), a profound, acute, disseminate and focal encephalomyelitis characterized by intense vascular engorgement, perivascular and parenchymatous cellular infiltration and extreme degenerative changes in the nerve cells. In chick embryo, excessive increase of virus continuing until just before host's death, virus being found eventually throughout the egg but most concentrated in the embryo; vaccines made from virus grown in chick embryo and then inactivated are especially effective because of the high titer of virus represented in them; increased resistance with age characteristic of chorioallantoic membrane as well as of hatched chick; rounded acidophilic masses occur usually near periphery of nucleus in embryonic nerve cells; no such inclusions are found as a result of infection with Borna disease virus or poliomyelitis virus.

**Transmission.** Experimentally by tick, *Dermacentor andersoni* Stiles (*IXODIDAE*), passing through eggs to offspring; this tick is infective to susceptible animals on which it feeds as larva, nymph or adult. Experimentally by *Aedes aegypti* L. (to guinea pig and horse, preinfective period 4 to 5 days; insects retain virus for duration of life, not to eggs of infected mosquitoes; not passed from males to females or by males from female to female), *A. albopictus*, *A. atropalpus*, *A. cantator*, *A. dorsalis*, *A. nigromaculis*, *A. sollicitans*, *A. taeniorhynchus*, *A. triseriatus*, and *A. vexans* (*CULICIDAE*). *Triatoma sanguisuga* (Le Conte) (*REDUVIIDAE*) has been found infected in nature and has transmitted virus experimentally to guinea pigs. The American dog tick, *Dermacentor variabilis* Say (*IXODIDAE*) has been infected by

inoculation, not by feeding; it has not been shown to transmit.

**Serological relationships:** Neutralizing antibodies are formed as a result of vaccination with inactive, formalized virus; antigenicity of formalin-inactivated virus as well as of active virus is blocked in the presence of antiserum. In rabbit, cerebral resistance is coincident with presence of neutralizing antibody in spinal fluid. In guinea pig, therapy with specific antiserum ineffective if begun after onset of encephalitis; effective if begun within 24 to 48 hours of peripheral inoculation. No cross neutralization reaction with lymphocytic choriomeningitis virus, Japanese B encephalitis virus or St. Louis encephalitis virus. Constituent strains (typical Western and Eastern) do not give cross neutralization reactions, but do show the presence of common antigens by cross reactions in complement fixation not shared with such other viruses as Japanese B encephalitis virus, St. Louis encephalitis virus, West Nile encephalitis virus, lymphocytic choriomeningitis virus. Sera of human cases may be negative by complement fixation tests a few days after onset, yet strongly strain-specific during second week of illness.

**Immunological relationships:** Young of immunized guinea pigs are immune to homologous strain at least a month after birth. No cross immunity between Western and Eastern strains of equine encephalitis virus.

**Thermal inactivation.** At 60° C, not at 56° C, in 10 minutes.

**Filterability:** Passes collodion membranes 66, not 60, millimicrons in average pore diameter. Passes Berkefeld V, N, and W, finest Mandler, and Seitz filters.

**Other properties:** Inactivated below pH 5.5. Viable at least a year, dry in vacuum. Particle diameter estimated from filtration experiments to be 20 to 30 millimicrons. Electron micrographs show particles as spherical or disk-shaped, about 30 millimicrons in diameter with round or oval region of high density within each, older preparations show

Attack phenol and cresol at times, also naphthalene.

Aerobic, facultative.

Optimum temperature 25°C.

Habitat: Manure and soil.

45. *Pseudomonas dacunhae* Gray and Thornton. (Gray and Thornton, Cent. f. Bakt., II Abt., 73, 1928, 90; *Achromobacter dacunhae* Bergey et al., Manual, 3rd ed., 1930, 217.) From M. L. from the Island of d'Acunha.

Rods: 0.5 to 0.8 by 1.5 to 3.0 microns. Motile with one to six polar flagella. Gram-negative.

Gelatin colonies: Circular, whitish, raised, smooth, glistening, undulate

Gelatin stab: No liquefaction.

Agar colonies: Circular to amoeboid, white, flat, glistening, opaque, entire

Agar slant: Filiform, pale buff, raised, smooth, glistening, undulate

Broth: Turbid.

Nitrites produced from nitrates.

Starch not hydrolyzed.

No acid from carbohydrate media

Attack phenol.

Aerobic, facultative.

Optimum temperature 25°C.

Habitat: Soil.

46. *Pseudomonas arvilla* Gray and Thornton. (Gray and Thornton, Cent. f. Bakt., II Abt., 73, 1928, 90; *Achromobacter arvillum* Bergey et al., Manual, 3rd ed., 1930, 217.) From Latin, *arvum*, an arable field; M. L. dim. a little field.

Rods: 0.5 to 0.7 by 2.0 to 3.0 microns. Motile with one to five polar flagella. Gram-negative.

Gelatin colonies: Circular, whitish, convex, smooth, glistening, lobate

Gelatin stab: No liquefaction

Agar colonies: Circular or amoeboid, white to buff, flat to convex, smooth, glistening, opaque, entire.

Agar slant: Filiform, whitish, concave, smooth, ringed, entire.

Broth: Turbid.

Nitrites not produced from nitrates.

Starch not hydrolyzed.

Acid from glucose.

Attacks naphthalene.

Aerobic, facultative.

Optimum temperature 25°C.

Habitat: Soil.

47. *Pseudomonas salopium* Gray and Thornton. (Gray and Thornton, Cent. f. Bakt., II Abt., 73, 1928, 91; *Achromobacter salopium* Bergey et al., Manual, 3rd ed., 1930, 219.) From Latin, *Salop*, Shropshire.

Rods: 0.7 to 1.0 by 1.0 to 3.0 microns, occurring singly and in pairs. Motile with one to six polar flagella. Gram-negative.

Gelatin colonies: Circular, grayish-buff, flat, rugose or ringed, translucent border

Gelatin stab: No liquefaction

Agar colonies: Circular or amoeboid, white to buff, flat to convex, smooth, glistening, translucent border, entire.

Agar slant: Filiform, whitish, raised, smooth, glistening, lobate.

Broth: Turbid with pellicle.

Nitrites not produced from nitrates.

Starch not hydrolyzed.

Acid from glucose and sucrose

Attacks naphthalene.

Aerobic, facultative.

Optimum temperature 25°C.

Habitat: Soil.

48. *Pseudomonas minuscula* McBeth. (McBeth, Soil Science, 1, 1916, 437; *Cellulomonas minuscula* Bergey et al., Manual, 1st ed., 1923, 162.) From Latin dim. rather small.

Rods: 0.5 by 0.9 micron. Motile with one to two polar flagella. Gram-negative.

Gelatin stab: Moderate growth. Slight napiform liquefaction.

Agar colonies: Small, circular, slightly convex, butyrous becoming brittle, grayish-white, finely granular, entire.

Agar slant: Moderate, flat, grayish-white.

Broth: Turbid.

824; Jour. Bact., 33, 1937, 60; Am. Jour. Hyg., 32 (B), 1940, 19-23; 33 (B), 1941, 37-41; Jour. Exp. Med., 73, 1941, 507-529; Taylor et al., Jour. Inf. Dis., 67, 1940, 59-66; 69, 1941, 224-231; 72, 1943, 31-41; TenBroeck, Arch. Path., 25, 1938, 759 (Abst.); TenBroeck and Merrill, Proc. Soc. Exp. Biol. and Med., 31, 1933, 217-220; TenBroeck et al., Jour. Exp. Med., 62, 1935, 677-685; Traub and TenBroeck, Science, 81, 1935, 572; Tyzzer and Sellards, Am. Jour. Hyg., 33 (B), 1941, 69-81; Tyzzer et al., Science, 88, 1938, 505-506; van Roekel and Clarke, Jour. Am. Vet. Med. Assoc., 94 (N.S. 47), 1939, 466-468; Webster and Wright, Science, 88, 1938, 305-306; Wesselhoef et al., Jour. Am. Med. Assoc., 111, 1938, 1735-1740; Wright, Am. Jour. Hyg., 36, 1942, 57-67.

*S. Erro bornensis spec. nov.* From Borna, name of a town in Saxony where a severe epizootic occurred in 1894 to 1896.

Common name: Borna-disease virus.

younger), mouse; *Macaca mulatta* (Zimmermann) rhesus monkey.

Insusceptible species: Ferret, cat, pigeon; probably dog.

Geographical distribution. Wurtemberg, Germany, North and South America, Hungary, Russia, Belgium, France, Italy, Roumania.

Induced disease: In horse, encephalomyelitis characterized by lassitude, indifference to external stimuli; later intermittent excitement, difficulty in mastication and deglutition, spasms in various muscles, champing, excessive salivation; pupils unequal in size; paralysis of hindquarters, tail, muscles of tongue, or muscles of back; temperature usually normal; death in 20 to 37 hours or, less often, recovery after about 1 to 3 weeks. Virus may pass placenta and infect fetus in pregnant animals.

Transmission: To rabbit, experimentally by feeding and by injection intracerebrally, intraocularly, nasally, intravenously, subcutaneously, or intraperitoneally; not by living in same cage.

Immunological relationships: No cross immunity conferred by the Western strain of equine encephalomyelitis virus. Isolate of Borna disease virus from the horse immunizes rabbits against isolate from sheep, and *vice versa*. Herpes and rabies viruses do not immunize rabbits against subsequent infection by Borna disease virus.

Thermal inactivation: At 50 to 57° C in 30 minutes; at 70° C in 10 minutes.

Filterability: Passes Berkefeld N and Mandler filters, but with difficulty. Passes collodion membranes of average pore diameter 400 millimicrons readily, 200 millimicrons with difficulty, 175 millimicrons not detectibly. May be separated by differential filtration from louping-ill virus, which will pass even a 125-millimicron membrane.

Other properties: Particle size estimated from filtration data as 85 to 125 millimicrons. Optimum pH for stability in broth at 15 to 20° C is 7.4 to 7.6; very sensitive to greater alkalinity. Viable after 327 days dry at laboratory temperatures. Viable at least 6 months in 50 per cent glycerine. Inactivated by putrefaction in 5 days; by 1 per cent carbolic acid in 4, not in 2, weeks.

Literature: Barnard, Brit. Jour. Exp. Path., 14, 1933, 205-206; Covell, Proc. Soc. Exp. Biol. and Med., 32, 1934, 51-53; Elford and Galloway, Brit. Jour. Exp. Path., 14, 1933, 196-205; Howitt and Meyer, Jour. Infect. Dis., 54, 1934, 364-367; Nicolau and Galloway, Brit. Jour. Exp. Path., 8, 1927, 336-341, and in Medical Research Council, Special Report Series No. 121, London, 1928, 90 pp., Ann. Inst. Pasteur, 44, 1930, 673-696; 45, 1930, 457-523; Zwick et al., Ztschr. Infektionskr. parasit. Krankh. u. Hyg. d. Haustiere, 30, 1926, 42-136; 32, 1927, 150-179.

comma-shaped particles. Sedimentation constant, mean  $265.5 \times 10^{-12} \pm 5.4 \times 10^{-12}$  (range 232 to  $276 \times 10^{-12}$ ). Specific volume 0.861. Molecular weight of liponucleoprotein complex behaving as the virus calculated as 152 million, approximately 250 particles giving 50 per cent infection, material contains 4 per cent carbohydrate. Absorption of ultraviolet light reaches a peak at about  $2600 \text{ \AA}$ , a broad minimum at about  $2450 \text{ \AA}$ , and an increase at  $2200 \text{ \AA}$ .

**Strains** The Western strain (so-called Western equine encephalitis virus) may be considered as type of a large group of variants met in nature, some produce clinically milder disease than others (Birch, *Am Jour Vet Res*, 2, 1941, 221-226), they may change in virulence on passage in experimental hosts. The Eastern strain (so-called Eastern equine encephalitis virus) has been studied extensively also, and has been found to differ from the type strain especially in more rapid course of induced disease in the horse, in being experimentally transmissible to sheep, pig, dog, cat and the European hedgehog; in its localization in eastern coast states and absence from the area between California and Wisconsin, where the type strain is found, in failure experimentally to infect *Aedes aegypti* unless inoculated into body cavity by needle puncture, whereupon it persists and can be transmitted, and in failure of cross neutralization with the western strain. A strain produced by serial passage in pigeons is reported to have caused no obvious reaction in horses but to have induced the formation of neutralizing antibodies. A Venezuelan strain differs from the type in complement fixation reactions, it induces in man a mild disease, characterized by malaise, fever, headache or drowsiness, and uneventful recovery (Casals et al., *Jour. Exp. Med.*, 77, 1943, 521-530).

African monkey, by intracerebral, intranasal, and intraabdominal inoculation.

**Serological relationships:** Specific neutralizing antibodies arise after experimental infection in monkeys, but reinfection is not prevented; only a minority of human convalescent sera neutralize virus *in vitro*, the most potent sera probably being obtained from those with transient or light paralysis. Cross neutralization between monkey-passage and murine (cotton-rat and mouse) strains. No cross neutralization reaction with lymphocytic choriomeningitis virus. Isolates differ somewhat antigenically, homologous titers being higher than heterologous titers in some neutralization tests.

**Thermal inactivation** At or below 75° C in 30 minutes.

**Filterability** Passes membrane about 35, not 30, millimicrons in average pore diameter.

**Other properties.** Infectivity of virus maintained well at -76° C or in glycerine but poorly when dried or just frozen. Inactivated readily by hydrogen peroxide. Particle diameter estimated as about 12 millimicrons by filtration studies. Precipitated by half-saturated ammonium sulphate solutions. Electron micrographs show elliptical particles 20 to 30 millimicrons in diameter; impure infectious materials show long threads 20 by 75 to 500 millimicrons in size. **Component** probably virus has sedimentation constant  $S_{20}^0 = 62 \times 10^{-12}$  cm per sec. per dyne. Inactivated by potassium hydroxide, copper sulfate and potassium permanganate. Stable from pfi 2.2 to 10.4 for 2 hours at 37° C

Genus II. *Legio* gen. nov.

Viruses of the Poliovirus group, probably because of its

also obvious involution.

Latin *legio*, an army or legion.

The type species is *Legio debilitans* spec. nov.

Key to the species of genus *Legio*.

## I. Affecting man (see also IV below)

1. *Legio debilitans*.

2. *Legio crebica*.

3. *Legio simulans*.

## II. Latent in, or affecting, mouse

4. *Legio muris*.

## III. Affecting birds.

5. *Legio gallinae*.

## IV. Affecting swine and swineherds.

6. *Legio suariorum*.

1. *Legio debilitans* spec. nov. From Latin *debilitare*, to weaken or maim.

Common names: Poliomyelitis virus, virus of infantile paralysis.

Hosts. *HOMINIDAE*—*Homo sapiens* L., man. Experimentally, *Cercopithecus aethiops sabaeus*, green African monkey; *Macaca mordax*, *M. mulatta*, the rhesus monkey; *M. urus*, the cynomolgus monkey, mone monkey; for some isolates, *Sigmodon hispidus* Say and Ord, cotton rat; mouse, guinea pig; white rat.

Insusceptible species: Sheep ("refractory" but forms neutralizing antibodies), chicken.

Geographical distribution: Almost world-wide.

Induced disease: In man, probably subclinical in most cases, in view of the presence of specific antibodies in sera from the great majority of adults in all parts of the world; virus probably infects some part of the alimentary tract, being found in stools of most clinical cases, of most apparently healthy contacts, and even of some individuals who have recovered from abortive attacks (in one case 123 days after attack); clinical disease, largely in children, is characterized by invasion of central nervous system, with effects ranging from sore throat, fever,

vomiting, and headache to sudden and severe paralysis; the muscles most often involved are those of the legs, but there may be paralysis of abdominal or intercostal muscles. Virus not in urine or saliva, rarely in nasal washings, more often in stools of young than of old patients; in walls of pharynx, ileum, descending colon. Virus has been recovered from sewage. Incidence and fatality affected by racial characteristics, the first lower and the second higher in negroes than in whites in the United States. In monkey, similar disease, no virus in blood, relapse with reappearance of virus reported; in isolated intestinal loops, infection does not occur through normal mucosa in absence of intestinal contents, disease more severe in summer than in autumn, in autumn than in winter, more severe in older than in younger monkeys; no immunity follows inoculation unless obvious disease occurs.

Transmission: Transmission in milk has been suspected and at times confirmed. Virus has been recovered from mixed samples of flies in an epidemic area. No definite arthropod vector has been incriminated. Experimentally, in *Cercopithecus aethiops sabaeus*, the green

guinea pig tissues immunize the guinea pig but vaccines made from mouse tissues do not. Mice immune to this virus are susceptible to infection with pseudo-lymphocytic choriomeningitis virus and *vice versa*.

Thermal inactivation: At 55 to 56° C in 20 minutes.

Filterability: Passes Berkefeld V, N, and W filters and, with difficulty, a Seitz asbestos pad.

Other properties: Infective at least 206 days in storage at 4 to 10° C in 50 per cent neutral glycerine in 0.85 per cent saline. Infective particle calculated to be 37 to 55 millimicrons in diameter on the basis of centrifugation studies; 40 to 60 millimicrons by ultrafiltration tests. Inactivated by soap with loss of mouse-immunizing capacity.

3. *Legio simulans spec. nov.* From Latin *simulare*, to imitate, in reference to resemblance of this virus to the preceding in many respects, though not in size or antigenic properties.

Common name: Pseudo-lymphocytic choriomeningitis virus.

Hosts: *HOMINIDAE*—*Homo sapiens* L., man. Experimentally, also mouse, guinea pig, rhesus monkey; chorioallantoic membrane of chick embryo.

Induced disease In man, benign aseptic lymphocytic meningitis with virus in cerebro-spinal fluid; severe frontal headache, drowsiness, irritability, vomiting, eventual complete recovery. In mouse, experimentally, roughened fur, spontaneous tremor, hunched attitude, irritability, clonic movements ending with tonic convulsions on stimulation, temporary recovery from spasm with survival a few hours or instant death.

Serological relationships: Hyperimmune sera for lymphocytic choriomeningitis virus are ineffective for this virus, and *vice versa*. In man, after recovery, neutralizing antibody is strong at 1 month, fading before 7 months.

Immunological relationships: Mice acquire specific resistance to reinfection after experimental disease; mice immune to lymphocytic choriomeningitis virus are susceptible to pseudo-lymphocytic choriomeningitis virus and *vice versa*.

Thermal inactivation: At 56° C, not at 45° C, in 30 minutes.

Filterability: Passes Berkefeld V, not N, filter candle, Gradacol membrane of 320, not 300, millimicron average pore diameter.

Other properties: Particle diameter calculated to be not above 150 to 225 millimicrons, from filtration experiments.

2. *Legio cerebea* spec. nov. From Latin *cereus*, belonging to the Lower World.

Common names: Choriomeningitis virus, lymphocytic choriomeningitis virus.

Hosts: *MURIDAE*—*Mus musculus* L., gray or white mouse. *HOMINIDAE*—*Homo sapiens* L., man. *CERCOPITHECIDAE*—*Macaca mulatta*, rhesus monkey (experimentally, also guinea pig, white rat; dog (masked), ferret (masked), *Macaca irus*, crab-eating macaque, Syrian hamster; chick- or mouse-embryo serum-Tyrodé solution culture, chick embryo.

Insusceptible species: Pig, rabbit, field vole, bank vole, canary, hen, parakeet.

Geographical distribution: France, England, United States.

Induced disease: In white mouse, more virulent in young than in old individuals, infection may take place *in utero* or soon after birth, some mice become carriers after recovery, with virus in organs, blood, urine, and nasal secretions, carriers are immune to large intracerebral inoculations of virus, experimentally, 5 to 12 days after intracerebral inoculation of susceptible mice, somnolence, photophobia, tremors of the legs, tonic spasms of muscles in the hindquarters upon stimulation, recovery or death. In man, disease may be subclinical at times as shown by the fact that some supposedly normal sera contain specific antibodies, not all clinical cases develop protecting antibodies against testing strains, so that disease may be somewhat commoner than can be ascertained readily, in all cases benign, but in the more severe of these an acute aseptic meningitis, after incubation period of 1½ to 3 days, spells of fever extending as long as 3 weeks, late in the disease there may be a meningeal reaction both clinically and cytologically, lymphocytes and some large mononuclear cells appear in the meningeal fluids, although symptoms remain benign, there may be virus in the blood from the beginning of fever to the end of the second week, the

spinal fluid is not infective at first but may become so before there is a change in cell count, urine and saliva remain uninfected.

Transmission: In white mouse, by contact with mice infected when young, not with those infected when old; nasal mucosa considered portal of entry. In wild gray mouse of the same species, *Mus musculus*, by contact but less readily than in white mouse. Experimentally, by mosquito, *Aedes aegypti* L. (*CULICIDAE*), at 26 to 34° C, by bedbug, *Cimex lectularius* (*CIMIDAE*), but defecation on site of bitten area is essential, bite alone being ineffective. Experimentally, to guinea pig, by application of virus to normal and apparently intact skin; not by contamination of food or litter.

Serological relationships: Serum of recovered subjects usually neutralizes choriomeningitis virus. Hyperimmune serum is ineffective against pseudo-lymphocytic choriomeningitis virus and hyperimmune serum for that virus is ineffective in its turn when used with choriomeningitis virus. No cross neutralization with St. Louis encephalitis virus. A specific soluble antigen associated quantitatively with virus in all hosts fixes complement in the presence of immune serum, virus does so poorly if at all, the anti-soluble substance antibodies seem to be independent of virus-neutralizing antibodies. A soluble protein, readily separable from virus, gives a specific precipitin reaction with immune serum, antibodies concerned are probably not the virus-neutralizing antibodies.

Immunological relationships: Intraperitoneal injection of about 160 intracerebral lethal doses has been found to protect the white mouse against infection by subsequent intracerebral injection of 10,000 lethal doses. The immune mouse differs from the immune guinea pig in showing no neutralizing antibodies in its blood, even the guinea pig may develop resistance before antibodies appear in its serum. Formalized vaccines made from

Med., 65, 1937, 705-719; Theiler and Gard, *ibid.*, 72, 1940, 49-67, 79-90; Young and Cumberland, Am. Jour. Hyg., 37, 1943, 216-224

5. *Legio gallinae spec. nov.* From Latin *gallina*, hen.

Common names: Avian encephalomyelitis virus, infectious avian encephalomyelitis virus.

Host: *PHASIANIDAE*—*Gallus gallus* (L.), chicken (embryo not susceptible; in culture media, minced whole embryo in serum-Tyrode solution suffices to maintain virus, but embryo brain alone does not).

Insusceptible species: All tested species other than birds.

Geographical distribution: United States.

Induced disease: In chicken, fine or coarse tremors of whole body or only of head and neck or of legs; progressive ataxia, eyes dull, some loss of weight, weakness of legs, and progressive incoordination of leg muscles; somnolence precedes death, about 75 per cent die within 5 days of onset, 90 per cent within a week, the remainder showing a staggering, ataxic gait for weeks, some continuously tremulous; recovered birds, however, may produce eggs well, microscopic focal collections of glia cells, perivascular infiltration, degeneration of Purkinje's cells and degeneration of nerve cells; foci of infiltration throughout brain and spinal cord, virus not detected in the blood of affected chickens.

Transmission: Not through egg. Experimentally, by intracerebral injection.

Serological relationships: Specific antiserum neutralizes homologous virus but not the Eastern strain of equine encephalitis virus, antiserum specific for the latter does not neutralize avian encephalomyelitis virus.

Filterability: Passes Berkefeld V and N as well as Seitz 1 and 2 filters; also membranes 73 millimicrons in average pore diameter.

Other properties: Survives in 50 per cent glycerine for at least 88 days and frozen for at least 68 days. Infective particle estimated to be 20 to 30 millimicrons in diameter, by filtration studies

Literature: Jones, Science, 76, 1932, 331-332; Jour. Exp. Med., 59, 1934, 781-798; Kligler and Olitsky, Proc. Soc. Exp. Biol. and Med., 45, 1940, 680-683; Olitsky, Jour. Exp. Med., 70, 1939, 565-582; Olitsky and Bauer, Proc. Soc. Exp. Biol. and Med., 42, 1939, 634-636; Van Roebel et al., Jour. Am. Vet. Med. Assoc., 93 (N.S. 46), 1938, 372-375.

6. *Legio suariorum spec. nov.* From Latin *suaris*, swineherd.

Common name: Swineherds'-disease virus.

Hosts: *SUIDAE*—*Sus scrofa* L., swine. *HOMINIDAE*—*Homo sapiens* L., man. Experimentally, with fever as only symptom, white rat, cat, ferret, mouse; perhaps *Macaca mulatta* (Zimmermann), rhesus monkey.

Geographical distribution: Europe.

Induced disease: In man, a benign meningitis without sequelae, somewhat similar to lymphocytic choriomeningitis in man; cell counts in spinal fluids may be as high as 1200 to 1400; 4 to 7 (average 8) days after infection, fever lasting 3 to 21 days (average 9); sometimes conjunctivitis, more often a reddish maculopapulose eruption; severe sweating frequent; hemorrhagic tendency; blood in feces; recovery. Blood, urine, feces infectious, not spinal fluid or mucous excretions. Especially affecting young men, not often old men or women, among those having contact with swine or swine-producing quarters.

Transmission: Excreta of pigs, even as used for manure, are infective. Experimentally, to man, by subdermal or intramuscular injection.

Viable at least 1 month at 4° C, at least 1 year in 50 per cent glycerine. 40 days in 0.25 per cent phenol, 1 year when dried from frozen material. Inactivated by 0.05 per cent formalin at 4° C in 48 hours; by boiling in 5 minutes.

Literature: MacCallum et al., Brit. Jour. Exp. Path., 20, 1939, 260-269.

4. *Legio muris spec. nov.* From Latin *mus*, mouse.

Common names: Mouse-poliomyelitis virus, Theiler's-disease virus.

Host *MURIDAE*—*Mus musculus* L., white mouse

Insusceptible species *CERCOPITHECIDAE*—*Macaca mulatta* (Zimmermann), rhesus monkey.

Geographical distribution: United States, Japan, Germany, Palestine; probably widespread wherever white mice are raised.

Induced disease: In white mouse, ordinarily no obvious disease, virus occurring in feces and not being recoverable from thoracic or abdominal viscera or head (probable source is in abdominal wall, virus has been recovered most abundantly from intestinal contents, in moderate amounts from walls of intestine and in smaller concentration from mesenteric lymph glands), occasionally, individual mice show flaccid paralysis of hind legs, and brain or spinal-cord suspensions from these contain the virus, mice inoculated intracerebrally show flaccid paralysis in 7 to more than 30 days, first in one limb, later usually in all, the tail does not become paralyzed, very young inoculated mice may die without first showing paralysis, very old inoculated mice may become infected without showing obvious disease, some affected mice recover and those showing residual paralysis may become carriers of virus. In affected, experimentally inoculated mice, acute necrosis of ganglion cells of anterior horn of spinal cord, necrosis also of isolated ganglion cells of cerebrum. Later, marked neuronophagia. Perivascular infiltration in brain and spinal cord.

The reciprocal of the incubation period has been found approximately proportional to the logarithm of the amount of virus inoculated, thus serving to measure the concentration of samples of virus. Old mice less susceptible than young.

Transmission. Experimentally, by intracerebral, intranasal and intraperitoneal inoculation. Has been found to persist in adult flies, *Musca domestica* L. (*MUSCIDAE*) and other species, as long as 12 days after experimental feeding whereas mouse-adapted human poliomyelitis virus persists only 2 days in *Musca domestica* and not at all in some other species.

Serological relationships. Sera containing antibodies to the Lansing strain of human poliomyelitis virus fail to protect against mouse poliomyelitis virus.

Immunological relationships: Recovered mice are immune to various heterologous isolates or strains. No evidence of immunological relationship with virus of human poliomyelitis has been obtained, save that mice paralyzed with mouse poliomyelitis virus show some resistance to infection with the Lansing strain of human poliomyelitis virus, this has been interpreted as possibly no more than an interference phenomenon, since it seems to depend on actual prior lysis.

Filterability: Passes Berkefeld N and other Berkefeld filters and Chamberland L<sub>1</sub> filter

Other properties: Viable at least 14 months at -78° C, at least 150 days in 50 per cent glycerine at 2 to 4° C. Most stable near pH 8.0 and pH 3.3. Inactivated readily at 37° C by 1 per cent hydrogen peroxide. Particle diameter estimated as 0 to 13 millimicrons from filtration studies. Sedimentation constant,  $S_{11.5} = 100$  to  $170 \times 10^{-11}$  cm per sec. per dyne.

Literature: Bang and Glaser, Am. Jour. Hyg., 57, 1913, 320-321, Gahagan and Stevenson, Jour. Inf. Dis., 69, 1911, 232-237, Gard, Jour. Exp. Med., 72, 1910, 60-77, Gard and Pedersen, Science, 34, 1911, 433-434, Gildemeister and Ahlfeld,

of rabid horses or cattle. Not by contamination of food. In Brazil and Trinidad, probably by the vampire bat, which has been found infected in nature.

**Serological relationships:** Specific flocculation of rabies virus occurs in the presence of immune serum from rabbit or guinea pig; strains differ in relative amounts of antigenic constituents, as shown by absorption tests. Complement fixation occurs in the presence of virus and guinea-pig antiserum. Neutralizing antibodies are specific.

**Immunological relationships:** Virus exposed to ultraviolet light tends to lose its virulence before its immunizing potency. Passive immunization succeeds in white mice if antiserum is injected intracerebrally  $\frac{1}{2}$  hour before, but not 24 hours before or 2 hours after, virus. Chloroform-treated vaccines more effective than phenolized vaccines, but irritative.

**Thermal inactivation:** At 60 to 70° C in 15 minutes; in brain tissues, at 45° C in 24 hours.

**Filterability:** Passes Berkefeld V filter.

**Other properties:** Viable at least 2 months at 5° C in liquid or dry state. Infective particle between 100 and 240 millimicrons in diameter, by filtration studies.

**Literature:** Bernkopf and Kligler, *Brit. Jour. Exp. Path.*, 18, 1937, 481-485; Casals, *Jour. Exp. Med.*, 72, 1940, 445-451, 453-461; Covell and Danks, *Am. Jour. **NOTE:** The Negri body, a characteristic cell-inclusion in rabies, has been given the following names under the supposition that it represents stages in the life cycle of a protozoan parasite responsible for the disease: *Neurocytes hydrophobae* by Calkins, *Jour. Contagious Diseases* including Syphilis, 25, 1907, 510; *Encephalitozoon rabiei* by Manouelian and Viala, *Ann. Inst. Pasteur*, 38, 1924, 238, and *Glugea lyssae* by Levaditi, Nicolsu and Schoen, *Ann. Inst. Pasteur*, 40, 1926, 1948.

Serological relationships. Serum from recovered cases neutralizes the virus

Immunological relationships: Specific immunity follows attack of the disease

Filterability Passes Chamberland L<sub>2</sub> filter

Literature: Durand et al., Compt. rend. Acad. Sci., Paris, 203, 1936, 830-832, 957-959, 1032-1034; Arch. Inst. Pasteur de Tunis, 26, 1937, 213-227; 228-249, 27, 1938, 7-17.

### Genus III *Formido* gen. nov.

Viruses of the Rabies Group, inducing diseases characterized by involvement of the nervous system only Generic name from Latin *formido*, a frightful thing

The type and only recognized species is *Formido inexorabilis* spec. nov.

1 *Formido inexorabilis* spec. nov.

From Latin *inexorabilis*, implacable

Common name - Rabies virus

Hosts *CANIDAE*—*Canis familiaris* L., dog *FELIDAE*—*Felis catus* L., domestic cat, *F. nigripes*, black-footed cat, *F. ocreata*, wild cat. *HOMINIDAE*—*Homo sapiens* L., man. *MUSTELIDAE*—*Ictonyx orangeae*, polecat *SCIURIDAE*—*Geosciurus capensis*, ground squirrel *VIVERRIDAE*—*Cynictis penicillata*, yellow mongoose (yellow meercat), *Genetta felina* (Thunb.), genet cat, *Myonax pulchellus*, small, grey mongoose, *Suricata suricatta*, Cape suricate or common meercat Cattle, sheep, pig, horse, wolf *Cynalopex chama*, silver jackal *Phyllostoma supercilium*, vampire bat, *Desmodus rufus*, vampire bat, *Litibius planicostis trinitatis*, fruit-eating bat Experimentally, also *Mus musculus* L., white mouse, *Peromyscus polionotus polionotus* (Wagner), white footed mouse, tissue cultures of 5 or 6-day-old rat or mouse-embryo brain, chick embryo (allantois not regularly infected, but virus regularly reaches brain of embryo without injuring it, chick may hatch with titer of 1:100 or 1:1000 in brain) Chicken, mousehawk (*Buteo vulgaris*); pigeon, owl, goose, stork (*Ciconia ciconia*), pheasant (*Diardigallus diardi* B P)

In susceptible species Reptiles, fish No mammal is known to be susceptible.

Geographical distribution Almost world wide, absent only from relatively isolated countries or communities.

Induced disease In dog, after a short

incubation period (generally less than 10 days) altered behavior, hiding, lack of obedience, perverted appetite leading to ingestion of straw, paper, earth, and other unaccustomed materials, excitement, unprovoked biting (which may transmit the virus to new hosts), aimless wandering, excess salivation, progressive inability to swallow, alteration of bark to characteristic high pitched tone, staggering, paresis of hindquarters tending toward paralysis and involvement of anterior parts of the body, paralysis of lower jaw, muscular spasms, marked emaciation, death except perhaps in rare instances In man, after a relatively long incubation period depending on site of implantation (perhaps 27 to 61 days), a uniformly fatal disease, characterized by altered behavior, increased excitability, thirst, pharyngeal spasm with progressive inability to swallow, labored and noisy respiration, death in 3 or 4 days after onset, with or without paroxysm. In sheep, increased sexual desire, tendency to pull wool from other sheep or themselves; light butting, increasing until some ewes, after violent exercise, appear to faint, prostration within 1 to 4 days, death within 2 days from onset of locomotory paralysis. In mouse, experimentally, by intracerebral inoculation, apathy, sluggishness, roughening of hair, tremor, convulsions, prostration, death, sometimes flaccid paralysis of hind legs before death.

Transmission Usually by bite of dog or some closely related animal, occasionally by bites of cats, rarely by bites

Litmus milk: Acid, not digested.

Potato: No apparent growth.

Indole is formed.

Nitrites produced from nitrates.

Ammonia is produced.

Acid from glucose, lactose, maltose, sucrose and starch.

Aerobic, facultative.

Optimum temperature 20°C.

Habitat: Soil.

49 *Pseudomonas tralucida* Kellerman et al. (Kellerman, McBeth Scales and Smith, Cent. f. Bakt., II Abt., 39, 1913, 37; *Cellulomonas tralucida* Bergey et al., Manual 1st ed., 1923, 163) From Latin, clear, transparent.

Rods 0.6 by 1.2 microns. Motile with one or two polar flagella. Gram-negative.

Gelatin stab: No liquefaction.

Agar slant: Scant, grayish growth.

Broth: Turbid.

Litmus milk: Acid.

Potato: No growth.

Indole not formed.

Nitrites produced from nitrates.

Ammonia not produced

Acid from glucose, maltose, lactose, sucrose, starch, glycerol and mannitol.

Aerobic, facultative.

Optimum temperature 20°C.

Habitat: Soil.

50 *Pseudomonas mira* McBeth. (McBeth, Soil Science, 1, 1916, 437; *Cellulomonas mira* Bergey et al., Manual, 1st ed., 1923, 165.) From Latin, *mirus*, wonderful, extraordinary.

Rods: 0.4 by 1.6 microns. Motile with a single polar flagellum. Gram-negative.

Gelatin stab: Good growth. No liquefaction.

Agar colonies: Circular, convex, grayish-white, granular, lacerate

Agar slant: Moderate, flat, grayish-white, somewhat iridescent.

Broth: Turbid.

Litmus milk: Alkaline.

Potato: Moderate, grayish-white.

Indole not formed.

Nitrites produced from nitrates.

Ammonia is produced.

Acid from glucose, maltose, lactose, sucrose, starch, glycerol and mannitol.

Aerobic, facultative.

Optimum temperature 20°C.

Habitat: Soil.

51. *Pseudomonas lindneri* Kluver and Hoppenbrouwers. (Lindner, 50 Jubiläumsber. Westpreuss. Bot.-Zool. Vereins, 1928, 253; *Termobacterium mobile* Lindner, Atlas d. Mikrosk. Grundl. d. Garungsk., 3 Aufl., 2, 1928, Taf. 68; Kluver and Hoppenbrouwers, Arch. f. Mikrobiol., 2, 1931, 259; *Achromobacter mobile* Kluver and Hoppenbrouwers, *ibid.*, 258; not *Pseudomonas mobilis* Migula, Syst. d. Bakt., 2, 1900, 923.) Named for Lindner, the German bacteriologist who first studied this organism.

Short rods 1.4 to 2.0 by 4.0 to 5.0 microns. Occurring singly, in pairs and short chains. Motile with a single polar flagellum. Gram-negative.

Peptone gelatin: Poor growth.

Peptone agar: Poor growth.

Wort agar: White, round, raised colonies, 1 mm. in diameter. Good growth. Still better where 2 per cent sucrose, or yeast extract with sucrose is added. Chalk added to neutralize acid.

Broth: Poor growth in peptone or yeast extract broth unless sugars are added.

Carbon dioxide, ethyl alcohol and some lactic acid produced from glucose and fructose, but not from mannose. May or may not ferment sucrose. May produce as much as 10 per cent alcohol.

Catalase produced.

Anaerobic, facultative.

Optimum temperature 30°C.

Distinctive character: The fermentation resembles the alcoholic fermentation produced by yeasts.

Source: Isolated from the fermenting sap (pulque) of *Agave americana* in Mexico.

Habitat. Fermenting plant juices in tropical countries (Mexico).

## FAMILY IV. CHARONACEAE FAM. NOV.

Viruses of the Yellow-Fever Group, inducing diseases mainly characterized by fever and necrosis of tissues in the absence of obvious macule, papule, or vesicle formation or of conspicuous involvement of nerve cells.

## Key to the genera of family Charonaceae.

- I Viruses of the Typical Yellow-Fever Group.  
Genus I. *Charon*, p 1265.
- II Viruses of the Influenza Group  
Genus II *Tarpera*, p 1268.
- III. Viruses of the Hog-Cholera Group  
Genus III. *Tortor*, p 1275.

Genus I. *Charon* gen. nov.

Viruses of the Typical Yellow-Fever Group, inducing diseases mainly characterized by acute non-contagious fever. Vectors dipterous insects, so far as known. Generic name from Latin *Charon*, ferryman of the Lower World.

The type species is *Charon evagatus spec. nov.*

Key to the species of genus *Charon*.

- I Vectors mosquitoes
    - 1. *Charon evagatus*.
  - II Vectors unknown, perhaps mosquitoes
    - 2 *Charon tallia*
1. *Charon evagatus spec. nov.* From Latin *evagor*, to spread abroad.  
Common name Yellow-fever virus.  
Hosts HOMINIDAE—*Homo sapiens* L., man. Experimentally, also *Cercopithecus tantalus* Ogilby, *C. aethiops*, African guenon (asymptomatic), *Cercocebus torquatus* (Kerr), collared mangabey; *Mus musculus* L., mouse, *Microtus agrestis*, field vole, *Sciurus vulgaris* L., red squirrel, *Macaca mulatta* (Zimmermann), rhesus monkey, *Macaca sinensis* Indian crown monkey, *M. cynomolgus*, *M. speciosus*, *Eriomys europaeus*, hedgehog, *Gallus gallus* (L.), chicken (tolerant), *Dasypus aguti*, aguti (small porcupine).
- Insecticide susceptible species: Cat, ferret, rabbit, rat, *Cricetus auratus*, golden hamster, *Apodemus sylvaticus*, wood vole, *Eutamias glaucochus*, bank vole; pigeon, canary, pipistrelle bat, *Cricetomys gambianus*, pouched rat, dog, goat.
- Geographical distribution: Tropical re-
- gions in general, especially Central and South America, West Indies, West Africa, anti-mosquito campaigns have tended to eradicate yellow-fever virus from parts of its former range.
- Induced disease. In man, mild cases may occur, especially in natives where the disease is endemic, but in Europeans generally sudden fever without marked change in pulse rate after a 3 to 6-day incubation period, severe frontal headache, pains in the loin and legs and epigastric pain, gradual decrease in temperature to 98° or 99° F., weakening of pulse and slowing of heart beat in the absence of further temperature changes; jaundice, especially in sclerae, often in skin, albumen in urine, later bile-pigments also present, hemorrhages frequent especially in alimentary canal; fatty and necrotic changes in the liver; acute degeneration of renal parenchyma, splenic congestion; death may occur in the early acute state, but is more likely about the

fifth or sixth day; relapses may occur until 2 or 3 weeks after onset; case mortality varies from 10 to 90 per cent in different epidemics. A transitory immunity due to transfer of serum antibodies through the placenta protects offspring of immune mothers for a short time.

**Transmission:** By mosquitoes, *Aedes aegypti* L., *Aedes leucocelaemus* (D. and S.), *Haemagogus capricornis* Lutz (*CULICIDAE*). The mosquito *Aedes aegypti* becomes infective, after feeding on a suitable virus source, in 4 days at 37° C, 5 days at 36° C, 6 days at 31° C, 8 days at 25.1° C, 9 to 11 days at 23.4° C, 18 days at 21° C, and 36, not 30, days at 18° C; virus in head, thorax, and abdomen before bites are infective; no evidence of transmission of virus through eggs to offspring or to larvae eating infected adults. Experimentally, also by *Aedes scapularis* (Rondani), *A. fluviatilis* (Lutz), *A. luteocephalus*, *A. apico-annulatus* (*CULICIDAE*). Experimentally, by feeding, to *Macaca mulatta* and *Cercopithecus aethiops*; by rubbing infected blood into intact and unshaved skin of monkeys.

**Serological relationships** Complement-fixation and precipitating antibodies are specific.

**Immunological relationships:** A specific immunity develops after an attack of the disease or after vaccination with virus grown in media containing tissues of chick embryo minus head and spinal cord.

**Thermal inactivation:** At 55 to 60° C, not at 50° C, in 10 minutes

**Filterability:** Passes membranes of 55, and to some extent membranes of 50, millimicron average pore diameter. Passes Berkefeld V and N, as well as Chamberland F, filters.

**Other properties:** Particle estimated from filtration data to have a diameter of 17 to 28 millimicrons; by ultracentrifugation data, 19 millimicrons. Inactivated or inhibited by 30-minute exposure to 1:15 formalin, 1.6 ethyl alcohol; 1:300

yellowish eosin, 1:50 sodium oleate, 1:200 liquor cresolis compositus; viable after 30-minute exposure at 30° C to 1:7500 mercuric chloride, 1:150 phenol, 1:1500 hexylresorcinol, 1:150 sodium oleate. Sedimentation constant between 18 and 30  $\times 10^{-12}$  cm per sec. per dyne. Viable in 50 per cent glycerine at 2 to 4° C for 58, not for 100, days; in mouse brain at -8° C for 160 days. Viability may be lost on simple drying but retained if drying is carried on in vacuo over a desiccating agent.

**Strains:** Distinctive strains have been isolated. One, to which much study has been given, differs from the typical viscerotropic strain by possessing marked neurotropic or pantropic characteristics.

**Literature:** Bauer and Hughes, *Am. Jour. Hyg.*, 21, 1935, 101-110; Bauer and Mahaffy, *ibid.*, 12, 1930, 155-174; 175-195; Bugher and Gast-Galvis, *ibid.*, 39, 1944, 58-66; Bugher et al., *ibid.*, 39, 1944, 16-51; Davis, *ibid.*, 16, 1932, 163-176; Davis and Shannon, *ibid.*, 11, 1930, 335-344; Davis et al., *Jour. 2. *Charon vallis spec. nov.* From Latin *vallis*, valley.

Common name Rift Valley fever virus

Hosts *HOMINIDAE*—*Homo sapiens* L., man. *BOVIDAE*—*Bos taurus* L., cow; *Ovis aries* L., sheep, *Capra hircus* L., goat. Experimentally, also *Sciurus carolinensis*, grey squirrel, ferret, *Cricetus auratus*, golden hamster; *Apodemus sylvaticus*, wood mouse, *Microtus agrestis* field vole, *Muscardinus acellanarius*, dormouse, rat, mouse, *Macaca mulatta*, *M. irus*, *Cebus fatuellus*; *C. chrysopus*; *Hapale jacchus*; *H. penicillata*; *Cercopithecus callitrichus* (symptomless), *Erythrocebus palas* (symptomless); *Cercocebus fuliginosus* (symptomless), chick embryo in Tyrodé's solution, chorioallantoic membrane of chick embryo.

In susceptible species Horse, pig

Geographical distribution British East Africa.

Induced disease In man, benign disease, after 5½ to 6 days, rigors, pains in back, fever for 12 to 36 hours, followed by recovery, with persistence of acquired immune bodies as long as 4 to 5 years after infection. In sheep (lambs), dullness, rapid respiration, collapse and death in a few hours or a chronic course, focal necrosis in liver. In chorioallantoic membrane of chick embryo, experimen-

tally, areas of hyperplasia and of necrosis; connective tissue inflamed nearby; liver of embryo mottled with necrotic areas.

Transmission: Not by contacts. Mosquito, *Taeniorhynchus brevipalpis* (*CULICIDAE*), suspected as possible vector.

Serological relationships Antisera for psittacosis, dengue fever, and sandfly fever viruses fail to protect against infection with Rift Valley fever virus. Specific neutralizing antibody in intraperitoneally neutral mixture with Rift Valley fever virus may be dissociated so as to free virus by direct dilution in saline solutions, by intranasal inoculation, or by employment of a small dose, all methods probably implying a dilution effect.

Immunological relationships: No cross immunity with yellow-fever or dengue-fever viruses. If Rift Valley fever virus is inoculated into rhesus monkey simultaneously with yellow-fever virus, the animal tends to be protected against death from yellow fever (interference effect), but one-day earlier inoculation of Rift Valley fever virus does not protect.

Thermal inactivation At 56° C in 40, not 20, minutes.

Filterability: Passes Berkefeld V, N, and W filters; passes Chamberland Ia, Ia, Ia, Ia, Ia, and occasionally L<sub>11</sub> filters, passes membranes 150 millimicrons in average pore diameter freely, 90 millimicrons with difficulty, 70 millimicrons not at all.

Other properties Viable at least 8 months at 4° C, more than 4 weeks dry in liver tissues, 6 months in ½ per cent carbolic acid at 4° C. Diameter of infective particle estimated from filtration studies to be between 23 and 33 millimicrons.

Strains A neurotropic strain immunizes lambs without producing obvious illness, if given subcutaneously.

### Genus II. *Tarpeia* gen. nov.

Viruses of the Influenza Group, inducing diseases characterized principally by involvement of the respiratory tract. Generic name from Latin *Tarpeia*, name of a Roman maiden who treacherously opened a citadel to an enemy.

The type species is *Tarpeia alpha* spec. nov.

#### Key to the species of genus *Tarpeia*.

##### I. Infecting man principally.

1. *Tarpeia alpha*.
2. *Tarpeia beta*.
3. *Tarpeia premiens*.

##### II. Affecting feline species.

4. *Tarpeia felis*

##### III. Affecting domestic cattle (calves).

5. *Tarpeia vitulac*.

##### IV. Affecting canine species.

6. *Tarpeia canis*.
7. *Tarpeia vulpis*.

##### V. Affecting ferrets.

8. *Tarpeia viverrae*.

##### VI. Affecting domestic fowl.

9. *Tarpeia arium*.

1. *Tarpeia alpha* spec. nov. From first letter of Greek alphabet

Common name Influenza A virus; swine filtrate-disease virus.

Hosts: *HOMINIDAE*—*Homo sapiens* L., man *SUIDAE*—*Sus scrofa* L., domestic swine. Experimentally, also ferret, mouse, *Macacus irus*, hedgehog, rabbit (inapparent infection), guinea pig (inapparent infection), rat (inapparent infection); *Mustela sibirica* Milne-Edwards, Chinese mink; *Sciurotamias davidianus* Milne-Edwards, David's squirrel, chick embryo (some strains produce visible lesions at 36.5° C on chorioallantoic membrane); minced chick embryo in Tyrode's solution.

Insusceptible species: *Callosciurus caniceps canigenus* Howell, Chekiang squirrel; *Eutamias asiaticus senescens* Miller, chipmunk.

Geographical distribution: World-wide.

Induced disease: In man, headache, dizziness, with shivering and muscular pains; rise of temperature on the second day, sometimes with fall on the third and elevation again later; often complicated by bronchitis and bronchopneumonia; hemorrhagic and edematous lobular consolidation in lungs; virus most easily recoverable from nasopharyngeal washings, but also from nasal secretions and lungs. In swine, virus alone produces only a mild malady (filtrate disease);

in the presence of *Haemophilus influenzae* suis a severe malady occurs under both natural and experimental conditions; it involves fever, cough, and prostration; many infected animals die. Lungworms, *Metastrongylus elongatus* and *Cherostongylus pudendotectus* (META-STRONGYLIDAE), from infected swine harbor virus at least 2 years, living meantime in earthworms, such as *Allotobophora caliginosa* (LUMBRICIDAE), which are eaten eventually by swine. The swine are refractory to viral infection during May, June, July, and August, but the disease may be invoked later by successive intramuscular injections of *Haemophilus influenzae* suis or other stimuli, such as feeding embryonated *Ascaris* ova. In infected swine, virus occurs in turbinates, tracheal exudates, and lungs, not in spleen, liver, kidney, mesenteric lymph nodes, brain, blood, or mucosa of colon. Neutralizing antibodies appear later (7th to 10th day) in the mild filtrate disease than in typical swine influenza, in which they appear about the 6th to the 7th day, maximum titer on 11th to 27th day. Experimentally in mouse, not contagious as in swine and not dependent on the coexistence of a bacterial component, death of epithelium of respiratory and terminal bronchioles, complete epithelial desquamation, dilatation of bronchioles, collapse of alveoli, in healing, widespread epithelial proliferation. Experimentally in ferret, moderate apathy, lack of appetite, pallor of nose, variable catarrhal symptoms, at acute stage of disease, necrosis of respiratory epithelium of nasal mucous membrane, with desquamation of superficial cells, exudation into air passages and inflammatory reaction in the submucosa, repair follows, beginning on the 6th day after infection and becoming essentially complete at the end of 1 month, after recovery the ferret is immune for 3 months or more with subsequent waning of resistance, subsequent subcutaneous inoculations of virus restore immunity.

Transmission: Presumably by droplets; for example between cages of ferrets as close as 5 feet apart, even to levels 3 feet higher than cage of diseased individuals. Experimentally, from washings of human throats to ferret, mouse, chick embryo (by amniotic route and to allantoic membrane); in mice, by contact and by inhalation of fine droplets.

Serological relationships: Neutralizing antibodies common in human sera from individuals above 10 years of age; rarer in sera from young children; strongly effective for homologous, weak for heterologous, virus in convalescent sera. Soluble complement-fixing antigen of swine strain has components in common with antigens of human strains (PR8 and WS). Complement fixation best 10 to 14 days after onset in man. Inactivating capacity of nasal secretions proportional to level of neutralizing antibodies in blood. Agglutination of red cells by influenza virus is inhibited quantitatively by specific antiserum.

Immunological relationships. Specific immunization of ferrets, without obvious disease, occurs as a result of intranasal inoculation of egg-passage influenza virus that is not transmissible from ferret to ferret. In mice, immunizing dose is directly proportional to degree of induced immunity, immunity to the strain used in immunization is more effective in general than that to heterologous isolates of the virus.

Filterability. Passes Berkefeld V filter.

Other properties. Particle size estimated as 80 to 120 millimicrons by filtration studies, 80 to 90 millimicrons by ultracentrifugation ( $S_{20,0} = 721 \times 10^{-11}$  cm per sec per dyne), electron micrographs show bean or kidney-shaped particles, or round particles with central dense spot, averaging 77.6 millimicrons in diameter. Inactivated by oleic, lipoic and linoleic acids without loss of immunizing ability. Inactivated by ultraviolet radiation.

2. *Tarpeia beta spec. nov.* From second letter of Greek alphabet.

L.,  
mouse, chick embryo.

Geographical distribution: United States, England.

Induced disease: In man, subclinical disease or one resembling that induced by influenza A virus. In chick embryo, experimentally, virus increases in endodermal cells lining allantoic cavity.

Serological relationships: Not neutralized by antiserum to influenza A virus. Specific neutralization and complement-fixation reactions. Rapidly adsorbed by normal chicken-blood red cells (95 per cent in 15 minutes), released in 4 hours essentially completely; the process is then repeatable with fresh red cells.

Other properties: Particle circular or bean-shaped in outline, with average diameter of 97.3 millimicrons in electron micrographs; of 99.8 millimicrons by centrifugation studies.

Literature: Burnet, Austral. Jour. Exp. Biol. and Med. Sci., 13, 1941, 291-295; Francis, Science, 82, 1940, 405-408; Proc. Soc. Exp. Biol. and Med., 45, 1940, 861-863; Hirst, Jour. Exp. Med., 76, 1942, 195-209; Lush et al., Brit. Jour. Exp. Path., 22, 1941, 302-304; Nigg et al., Am. Jour. Hyg., 35, 1942, 265-284; Sharp et al., Jour. Immunol., Virus Res. and Exp. Chemother., 48, 1944, 129-153.

3. *Tarpeia premens spec. nov.* From

virus.  
apiens

L., man. Experimentally, also chimpanzee, chick embryo.

Geographical distribution: World-wide except in conditions of isolation of small communities

Induced disease In man, incubation period about 48 hours; mild malady; running nose in 81 per cent of cases, obstruction of nostrils in 44 per cent, sudden onset in 37 per cent, cough in 31 per cent, headache in 19 per cent, sore throat in 14 per cent, fever in 13 per cent, inflammation of eyes in 12 per cent; changes in weather, especially during a warm season, predispose to the disease, no correlation between susceptibility and outdoor exercise, exposure to fresh air while sleeping, eye color, adenotonsillectomy, or size of frontal sinus. Incidence inversely proportional to daily hours of sunshine and atmospheric temperature. Fitness (defined by speed of oxygen replacement) correlated with relative freedom from colds. Effect of rest during disease favorable, reducing complications, length of fever, duration of illness, and period off duty

Immunological relationships: After attack, specific immunity for about 7 weeks (minimum period 23 days), then exposure to chilling may cause a relapse, but an isolated community tends to lose the virus during the refractory period

Filterability Passes Berkefeld V and W as well as Seitz filters.

Other properties Viable at least 13 days at ice box temperature, anaerobically, at least 4 months frozen and dried in *vacuo*. Gum acacia tends to stabilize virus in chick-embryo tissue medium

Literature Dochez et al., Jour. Exp. Med., 63, 1936, 559-579, Doull et al., Am. Jour. Hyg., 13, 1931, 460-477, 17, 1933, 536-561, Galsfer, *ibid.*, 13, 1931, 771-780, 16, 1932, 213-210, 840-846, Jour. Inf. Dis., 51, 1932, 489-492, Galsfer and Doull, Am. Jour. Hyg., 18, 1933, 712-726, Hyde and Chapman, *ibid.*, 20, 1937, 116-123, Kierland et al., Proc. Soc. Exp. Biol. and Med., 35, 1936, 213-215, Le

Blanc and Welborn, Am. Jour. Hyg., 24, 1936, 19-24; Locke, Jour. Inf. Dis., 60, 1937, 106-112; Long and Doull, Proc. Soc. Exp. Biol. and Med., 28, 1930, 53-55. Maughan and Smiley, Am. Jour. Hyg., 9, 1929, 466-472; Noble and Brainard, Jour. Bact., 29, 1935, 407-409, Palmer, Am. Jour. Hyg., 16, 1932, 221-232, Paul and Freese, *ibid.*, 17, 1933, 517-535; Shibley et al., Jour. Am. Med. Assoc., 95, 1930, 1553-1556; Smiley, Am. Jour. Hyg., 6, 1926, 621-626, 9, 1929, 477-479.

4. *Tarpela felis spec. nov.* From Latin *felis*, cat

Common name: Feline-distemper virus.

Hosts. FELIDAE—*Felis catus* L., domestic cat, *F. pardus*, leopard; *F. tigrina*, American tiger cat, *F. aurata*, African tiger cat; *F. planiceps*, rusty tiger cat; *F. marmorata*, marbled cat; *F. caracal*, caracal lynx; *F. pardalis*, ocelot; lion, tiger, puma relatively insusceptible.

Insusceptible species Man, dog, ferret, mongoose, rabbit, rat, mouse, guinea pig.

Induced disease In domestic cat, coughing, sneezing, running eyes and nose, with serous or purulent conjunctivitis, or diarrhea and vomiting, fever to 103 or 105° F; loss of appetite, general weakness, mortality high, especially among young individuals, death usually occurs on the 10th to the 12th day, in extreme cases, however, as early as the 5th or as late as the 35th day, catarrhal congestion in some part of the gastrointestinal tract is typical, this ranges from a few small patches in the ileum to involvement of the whole small intestine and parts of the large intestine or stomach and esophagus, often enlargement and congestion of abdominal lymph glands, enlargement of spleen, pleurisy, and peritonitis

Filterability Passes Berkefeld N and Chamberland L<sub>1</sub> filters.

Transmission By fomites.

Immunological relationships: Recovered cats specifically immune.

Other properties: Viable at least 3 weeks in 50 per cent glycerine; attenuated or killed by drying at room temperature, but some immunization is reported if dried virus is injected.

Literature: Dalling, Vet. Record, 16, 1935, 283-289; Findlay, Vet. Jour., 89, 1933, 17-20; Hindle and Findlay, Jour. Comp. Path. and Therap., 45, 1932, 11-26; Verge and Cristoforoni, Compt. rend. Soc. Biol., Paris, 99, 1928, 312-314.

5. *Tarpeia vitulae spec. nov.* From Latin *vitula*, cow-calf.

Common name: Pneumoenteritis virus

Hosts: BOVIDAE—*Bos taurus* L., domestic cattle. Experimentally, also MURIDAE—*Mus musculus* L., mouse.

Geographical distribution: United States.

Induced disease: In cattle (calves), after incubation period of 2 to 4 days, fever increasing rapidly to 40 or 41° C and lasting 3 to 5 days; usually after first day of fever, diarrhea with feces soft, yellow, voluminous, fetid in odor, occasionally blood-tinged or fluid; diarrhea is followed by pneumonia and recovery after disappearance of fever; catarrhal enteritis and a bronchopneumonia usually confined to the anterior lobes of the lungs underlie the symptoms, no inclusion bodies in cells of affected tissues.

Transmission. By pen contacts with infected calves. Experimentally, by intranasal inoculation of calves, using inocula prepared from lungs of infected mice.

Serological relationships. Recovered animals develop neutralizing antibodies.

Immunological relationships: A specific resistance to reinfection is conferred by an attack of the disease.

Filterability: Passes Berkefeld N filter.

Literature: Baker, Cornell Vet., 32, 1942, 202-204; Jour. Exp. Med 78, 1943, 435-446.

6. *Tarpeia canis spec. nov.* From Latin *canis*, dog.

Common name: Canine-distemper virus.

Hosts: CANIDAE—*Canis familiaris* L., dog; *Vulpes* sp., fox. MUSTELIDAE—ferret.

Insusceptible species: Man, rabbit, guinea pig, white rat, cat.

Geographical distribution: Widespread throughout the world.

Induced disease: In dog, after 4 days from time of infection, fever and a watery discharge from the eyes and nose, sometimes inconspicuous but often profuse; usually diarrhea and wasting followed by recovery or, exceptionally, death. Virus passes from the respiratory tract through the blood stream to its favored sites in vascular endothelium and cells of the reticulo-endothelial system. Nuclear inclusions are found in liver cells, bronchial epithelial cells, glandular cells of the stomach and intestine, and bile-duct epithelial cells; there are also cytoplasmic inclusions in bile-duct epithelial cells.

Transmission: By contact. Probably by air-borne droplets. No arthropod vector is recognized.

Immunological relationships: Dead-vaccine treatment followed by living-virus treatment produces a lasting immunity. Virus inactivated by photodynamic effect in 2 mm layer of 1:50,000 or 1:100,000 methylene blue, exposed 30 minutes at 20 cm from 100 candle-power lamp, still immunizes. Vaccine may be dried.

Filterability: Passes Chamberland L<sub>4</sub> and Mandler filters.

Other properties: Viable in liver tissue at 10° C for 35, not 85, days; in glycerine-saline solution at 10° C, 67 days though deteriorated, in vacuum-dried liver tissue, at 10° C, 90 days. If dried from frozen state, virus is viable in vacuum at least 430 days at 7° C, in oxygen-free nitrogen at least 365 days at 7° C. Viable in 25 per cent sterile horse serum at -21° C more than 693 days.

Literature: Carré, Compt. rend. Acad. Sci., Paris, 140, 1905, 689-690; Daldorf,

Jour. Exp. Med., 70, 1939, 19-27, De Monbreun, Am. Jour. Path., 13, 1937, 187-212; Dunkin and Laidlaw, Jour. Comp. Path. and Therap., 39, 1926, 201-212, 213-221; Green and Evans, Am. Jour. Hyg., 29 (B), 1930, 73-87; Laidlaw and Dunkin, Jour. Comp. Path. and Therap., 39, 1926, 222-230; 41, 1928, 1-17, 209-227, Perdrau and Todd, *ibid.*, 46, 1933, 78-89, Siedentopf and Green, Jour. Inf. Dis., 71, 1942, 253-259; Wharton and Wharton, Am. Jour. Hyg., 19, 1934, 189-216

7. *Tarpela vulpis spec. nov.* From Latin *vulpes*, fox.

Common name Fox-encephalitis virus  
Hosts CANIDAE—*Vulpes* sp., silver fox Experimentally, also some, but not all, dogs, coyote.

Insusceptible species Gray fox, mink, ferret, sheep, laboratory rabbit.

Geographical distribution United States

Induced disease. In fox, after 2 days from time of infection, loss of appetite, slight nasal discharge; convulsions with early death or hyperexcitability, blind walking, lethargy, flaccid or spastic paralysis, muscular twitching, fearfulness, weakness, coma and death, many more foxes become infected in epizootics than show obvious disease, some being symptomless carriers, 12 to 20 per cent fatalities may be experienced among young foxes on ranches, 3 to 9 per cent among adults. Intranuclear inclusions in vascular endothelial cells especially in cerebral endothelium, sometimes in hepatic cells and endothelial cells of liver and kidney, no intracytoplasmic inclusions, virus in heart blood, spleen, and brain, in carriers, virus is believed to persist in focal lesions in upper respiratory tract. Experimentally in susceptible dogs, sometimes coryza, discharge from eyes and nose often purulent, commonly fits of excitement, coma, death, recovery rare, cellular infiltration in the central nervous system, focal necrosis of the liver, specific

intranuclear inclusions in cells of the vascular endothelium, meningeal cells, reticulo-endothelium, hepatic cells, and occasionally in cortical cells of the adrenal.

Transmission. Experimentally, by skin scarification, intramuscular injection, intraperitoneal injection, inoculation of cisterna, intratesticular injection, inoculation of nasal cavity; not by corneal scarification.

Immunological relationships: Injections of this virus afford no immunity to subsequent infection by canine distemper virus.

Filterability: Passes Berkefeld N filter.

Other properties: Viable in 50 per cent glycerine for several years, in carcass for several days.

Literature Barton and Green, Am. Jour. Hyg., 37, 1943, 21-36, Green, Proc. Soc. Exp. Biol. and Med., 23, 1926, 677-678, Am. Jour. Hyg., 13, 1931, 201-223; Green and Dewey, Proc. Soc. Exp. Biol. and Med., 27, 1929, 129-130; Green and Evans, Am. Jour. Hyg., 29 (B), 1930, 73-87, Green and Shillinger, *ibid.*, 19, 1931, 362-391, Green et al., *ibid.*, 12, 1930, 109-129, 14, 1931, 353-373; 18, 1933, 462-481, 19, 1934, 343-361, 21, 1935, 366-388, 24, 1936, 57-70, Lucas, Am. Jour. Path., 16, 1940, 739-760.

8 *Tarpela viverrae spec. nov.* From Latin *viverra*, ferret.

Common name Ferret-distemper virus

Host MUSTELIDAE—*Mustela furo*, ferret

Insusceptible species Dog, mouse, rat, guinea pig, rabbit.

Geographical distribution United States.

Induced disease. In ferret, fever to 105 or 106° F, lethargy, loss of appetite, conjunctivitis with exudate closing eyes, sometimes a purulent nasal discharge, weight loss small, sneezing rare, difficulty in breathing, death 14 to 50 days after inoculation (average 20 days), sometimes

preceded by convulsions and other nervous signs; fatality rate 70 to 100 per cent.

Transmission: By cage contacts. By feeding. Experimentally by intranasal, subcutaneous, or intradermal inoculation.

Immunological relationships: In immunized animals, no cross immunity with canine distemper virus nor with human influenza virus.

Thermal inactivation: At 60° C in 30 minutes.

Filterability: Passes Berkefeld N filter.

Other properties: Viable at least 3, but not 5, months in 50 per cent neutral glycerine; at least 4 months when frozen and dried *in vacuo*.

Literature: Slanetz and Smetana, Jour. Exp. Med., 66, 1937, 653-666; Spooner, Jour. Hyg., 38, 1938, 79-89.

9. *Tarpeia avium spec. nov.* From Latin *aves*, fowl of the air.

Common names: Laryngotracheitis virus; also known as infectious laryngotracheitis virus and as infectious bronchitis virus.

Hosts: PHASIANIDAE—*Gallus gallus* (L.), chicken. Experimentally, also PHASIANIDAE—pheasant;  $F_1$  hybrid between male Ringneck pheasant and female bantam chicken; chorioallantoic membrane of developing chicken embryo (with macroscopic lesions on membrane as a result of proliferative and necrotic changes); turkey embryo

Insusceptible species: Guinea fowl (no evidence of disease on inoculation); white rat, guinea pig, rabbit; embryos of pigeon, guinea fowl, and duck.

Geographical distribution: United States, Canada, Australia.

Loss of appetite, moribund

both eyes, respiratory distress, hemorrhagic and mucous exudate in lumen of trachea and occasionally in the bronchi; death as a result of asphyxiation or, more often, recovery, recovered birds occasionally carry the virus in the upper

respiratory tract for some time (a period of 467 days has been recorded); virus is not found on eggs during an outbreak in a flock, but is always in trachea of an affected bird; intranuclear inclusions in tracheal lesions; virus has special affinity for mucous membrane of eye, nostril, larynx, trachea, cloaca, and bursa of Fabricius; usually affects more than half the birds in a flock, with a mortality of 5 to 60 per cent (averaging between 10 and 20 per cent).

Transmission: By contacts. Experimentally, by intrabursal injection (in bursa of Fabricius) or by rubbing the mucous membrane in the dorsal region of the outer or proctodeal part of the cloaca with a small cotton swab moistened with a suspension of virus.

Serological relationships: Serum from recovered fowl neutralizes virus; dilution tends to reactivate neutralized virus.

Immunological relationships: Experimental infection of cloaca and bursa of Fabricius, especially in 2 to 4-month-old birds, immunizes against infection by subsequent tracheal inoculation.

Thermal inactivation: At 55.5° C in 10 to 15 minutes; at 60° C in 2 to 3 minutes; at 75° C in  $\frac{1}{2}$  to  $\frac{3}{4}$  minute; all tests with virus in the presence of tracheal exudate.

Filterability: Passes Berkefeld V and N filters.

Strains: A Victorian strain has been reported as of low virulence for fowls.

Other properties: Inactivated in 5 per cent phenol in 1 minute; in 3 per cent cresol compound in  $\frac{1}{2}$  minute; in 1 per cent sodium hydroxide in  $\frac{1}{2}$  minute. Viable in tracheal fluid in dark for 75, not 110, days; in light for 6, not 7, hours; in buffer solution at pH 7.4 for 131 days; at 4 to 10° C in dark for at least 217 days; in dried state for at least 661 days. Viable in dead body at 37° C for 22, not 44, hours; at 13 to 23° C for 10, not 15, days; at 4 to 10° C for 30, not 60, days.

Literature: Beach, Science, 72, 1930, 633-634; Jour. Exp. Med., 54, 1931, 800-816; Jour. Inf. Dis., 57, 1935, 133-135;

52. *Pseudomonas membranoformis* (Zobell and Allen) Zobell. (*Achromobacter membranoformis* Zobell and Allen, Jour. Bact., 29, 1935, 246; Zobell, Jour. Bact., 48, 1943, 45) From Latin *membrana*, membrane, and *forma* having the form of.

Rods: 0.9 to 1.2 by 3.5 to 4.8 microns, occurring singly and in pairs. Motile with lophotrichous flagella. Encapsulated. Gram-negative

Gelatin stab: Growth filiform, best at top, with slow crateriform liquefaction

Agar colonies: Circular, 1.0 to 2.5 mm, with crinkled surface.

Agar slant: Moderate, beaded, raised growth. Membranous consistency. Becomes browned with age.

Broth: Slight turbidity, flocculent sediment, film of growth on walls of test tube

Milk: No growth.

Potato: No growth.

Indole not formed.

Nitrites not produced from nitrates.

No H<sub>2</sub>S produced.

Acid but not gas from glucose, sucrose, dextrin and mannitol. No acid from lactose or xylose.

No diastatic action.

Optimum temperature 20° to 25°C.

Aerobic.

Source: Sea water

Habitat: Sea water.

53. *Pseudomonas marinoglutinosa* (Zobell and Allen) Zobell. (*Achromobacter marinoglutinosus* Zobell and Allen, Jour. Bact., 29, 1935, 246; Zobell, Jour. Bact., 46, 1943, 45). From Latin *marinus*, pertaining to the sea, and *glutinosus*, full of glue, sticky

Short rods. 0.7 to 1.0 by 1.8 to 2.4 microns, with rounded ends, occurring singly, in pairs and in clumps. Motile with polar flagella. Staining granular.

Gram-negative

Indole not formed.

Nitrites are produced from nitrates.

Starch hydrolyzed.

Agar colonies: Round with concentric

circles and crinkled radial lines, 1.5 to 5.0 mm in diameter. No pigment.

Agar slant: Moderate, filiform, flat. Butyrous consistency.

Broth: Moderate clouding, marked ring, adherent film of growth on test tube wall, and flaky sediment.

Milk: No growth.

Potato: No growth.

Indole not formed.

Nitrites not produced from nitrates.

Hydrogen sulfide and ammonia produced from Bacto-tryptone.

Acid but not gas from xylose and dextrin. No acid from glucose, lactose, sucrose and mannitol.

Starch is hydrolyzed.

Optimum temperature 20° to 25°C.

Aerobic, facultative

Source: Sea water.

Habitat: Sea water.

54. *Pseudomonas gelatica* (Gran) Bergey et al. (*Bacillus gelaticus* Gran, Bergens Museums Aarbog, 1902, 14; *Bacterium gelaticum* Lundestad, Cent. f. Bakt., II Abt., 75, 1923, 323; Bergey et al., Manual, 3rd ed., 1930, 175.) From French, like gelatin

Rods, with rounded ends, 0.6 to 1.2 by 1.2 to 2.6 microns, occurring singly, in pairs, and sometimes in short chains. Motile. Gram-negative.

Fish-gelatin colonies: Circular, transparent, glistening, becoming brownish in color.

Fish-gelatin stab: Liquefaction infundibuliform, with greenish color.

Sea-weed agar colonies: Circular, flat, entire, glistening, reddish-brown center with grayish-white periphery. Liquefied.

Fish-agar slant: Flat, transparent streak, with undulate margin, reddish-brown.

Broth: Turbid with flocculent pellicle, and greenish-yellow sediment.

Indole not formed.

Nitrites are produced from nitrates.

Starch hydrolyzed.

in minced swine testicle on solid serum-agar and on egg membrane, increase being limited to the living tissues from the swine and furnishing inoculum active in amounts as small as  $10^{-8}$  ml.

**Transmission:** By feeding. Through air contamination. Rarely by contact. Experimentally, by subcutaneous injection. Urine highly infective. Virus in blood and all tissues early in disease.

**Serological relationships:** Immune serum affords passive protection.

**Thermal inactivation:** At  $55^{\circ}\text{C}$  in 30 minutes; at  $60^{\circ}\text{C}$  in 10 minutes. At  $72^{\circ}\text{C}$  in 1 hour in dried blood.

**Filterability:** Passes Berkefeld filter.

**Other properties:** Viable in blood in cool, dark place at least 6 years.

**Literature.** De Koeck et al., *Onderstepoort Jour. Vet. Sci. and Anim. Indust.*, 14, 1910, 31-93; Hecke, *Cent. f. Bakt., I Abt., Orig.*, 126, 1932, 517-526; Montgomery, *Jour. Comp. Path. and Therap.*, 34, 1921, 159-191; Röhrer, *Arch. Tierheilk.*, 62, 1930, 345-372, 439-462; 64, 1931, 124-143, TenBroeck, *Jour. Exp. Med.*, 74, 1941, 427-432.

2. *Tortor bovis spec. nov.* From Latin *bos*, cow.

**Common names** Cattle-plague virus, virus of pestis bovina, rinderpest virus, Rinderpest virus.

**Hosts:** *BOVIDAE*—*Bos taurus* L., domestic cattle; swine, buffalo, zebu cattle, sheep, goat, camel, deer. Koedoe, eland, bushbuck, duiker, and other antelopes.

**Insusceptible species:** Man, solipeds, carnivora.

**Geographical distribution.** Widespread over Asia and the Asiatic islands. At times in Western Europe. Enzootically in Turkey. Periodically in North Africa, especially in Egypt; at times throughout Africa. Not in North America. At times in South America, Australia (suppressed quickly).

**Induced disease.** In domestic cattle, after 3 to 9 days, febrile reaction, restlessness, loss of appetite, cessation of rumina-

tion; fever highest at 5th or 6th day of disease, then temperature drops to normal or subnormal and diarrhea begins; muzzle dry, coat staring, hair dull, skin moist in parts; twitching of superficial muscles, grinding of teeth, arching of back, glairy discharge from nose, redness of mucous membranes; restlessness increases, diarrhea becomes severe with fetid, blood-stained or blackish liquid discharges; weakness, drooping of ears, occasional yawning, coldness of extremities; occasionally excitement precedes weakness; skin may become red and moist, showing protuberances and vesicles, with matted hair; later wrinkling and scab formation; conjunctiva red, eyelids swollen, tears flowing, followed by mucous, then purulent, discharge; sometimes a cough develops and respirations become rapid; red spots inside mouth develop into erosions or ulcers, often confluent; pregnant animals often abort; milk of cows decreases, sometimes becoming yellow and watery. Death is sometimes early (1 to 2 days after first manifestations of disease), more often delayed (4 to 7 days); sometimes animals live 2 or 3 weeks or longer. Disease milder and more chronic where enzootic; morbidity to 100 per cent and mortality to 96 per cent in new areas. Recovered animals show a lasting, sterile immunity. Urine, feces, nasal and lachrymal discharges, sweat, aqueous humour, cerebrospinal fluid, lymph, emulsions of viscera and muscles, and blood are infective during the course of the disease.

**Transmission.** By contact, even during prodromal period; by contaminated food, troughs, or other articles. No insect vector is known.

**Immunological relationships.** One attack confers a lasting immunity, except rarely, when a mild second attack may occur. A calf from a diseased mother may be resistant if pregnancy was far advanced when the disease occurred.

**Filterability:** Passes Berkefeld V filter candle, with difficulty.

**Other properties:** Remains infective at

### Genus III. *Tortor* gen. nov.

Viruses of the Hog-Cholera Group inducing diseases characterized by involvement of many tissues. Generic name from Latin *tortor*, tormentor.

The type species is *Tortor suis* spec. nov.

#### Key to the species of genus *Tortor*.

#### I In mammals.

##### A. Infecting swine.

##### B. Infecting cattle.

##### C. Infecting the horse.

##### D. Infecting sheep

##### E. Infecting cat

#### II In birds

##### 1. *Tortor suis*

##### 2. *Tortor bovis*

##### 3. *Tortor equorum*

##### 4. *Tortor equi*

##### 5. *Tortor oris*

##### 6. *Tortor felis*

##### 7. *Tortor galli*

##### 8. *Tortor furens*

1. *Tortor suis* spec. nov. From Latin *suis*, hog.

Common names Hog-cholera virus, swine fever virus

Host SUIDAE—*Sus scrofa* L., domestic swine Warthog (symptomless carrier).

In susceptible species. Dog, cat, cow, horse, donkey, sheep, goat, rabbit, guinea pig, mouse, rat, goose, hen, duck, pigeon

Geographical distribution Almost universal in pig breeding countries, espe-

cially in Europe, the British Isles, North and South America.

Induced disease In swine, after intramuscular injection, increased temperature and prostration within 2½ to 3 days; later lymph nodes enlarged, sometimes hemorrhagic, hemorrhages under capsule of kidneys. Virus may remain in blood of recovered pigs for 10 months. Acquired immunity is lasting, but most naturally infected animals die in newly infected herds. Virus has been cultured

Path. and Therap., 23, 1910, 315-325.

4. *Tortor equae spec. nov.* From Latin *equa*, mare.

Common name. Mare-abortion virus.

Hosts: *EQUIDAE*—*Equus caballus* L., horse. Experimentally, also Syrian hamster (newborn); tissues of human placenta grafted on the chorioallantois of the chick embryo.

Insusceptible species: Chicken (embryo; no observed susceptibility).

Induced disease. In horse, small, multiple, grayish white areas of necrosis in the livers of aborted fetuses, acidophilic intranuclear inclusions in hepatic cells around these foci, in epithelial cells of bile ducts, and in bronchial epithelium, petechial hemorrhages in the heart, spleen, and lungs; excess fluid in the thoracic cavity.

Transmission: By contact. By living in contaminated stalls.

Literature: Anderson and Goodpasture, Am. Jour. Path., 18, 1942, 555-561; Dimock, Jour. Am. Vet. Med. Assoc., 96, 1940, 665-666; Dimock and Edwards, Cornell Vet., 26, 1936, 231-240; Goodpas-

ture and Anderson, Am. Jour. Path., 18, 1942, 563-575; Hupbauer, Münch. Tierärztl. Wochenschr., 89, 1938, 37-38; Miessner and Harms, Deutsche Tierärztl. Wochenschr., 46, 1938, 745-748.

5. *Tortor ovis spec. nov.* From Latin *ovis*, sheep.

Common name: Blue-tongue virus

Hosts: *BOVIDAE*—*Ovis aries* L., sheep; *Bos taurus* L., cattle.

Geographical distribution: South Africa.

Induced disease: Both sheep and cattle may carry the virus at times without obvious manifestations of disease or there may be severe manifestations. In sheep, experimentally, diffuse hyperemia of buccal mucosa, especially of lips; then petechiae and ecchymoses followed by exoriations and necrosis of the mucous membrane, especially on lips, tongue, inside of cheeks, dental pad, gums, muzzle, and external nares; sometimes deep seated necrotic ulcers on tongue developing from the more usual superficial necrotic process; mucoid discharge from nostrils, becoming muco-hemorrhagic; commonly frothing at the mouth in early stages of the disease; frequently reddening of skin of lips and nose; rarely whole skin becomes flushed and wool is shed; often swelling of vulva with necrotic changes on borders and petechiae in mucosa; tongue sometimes swollen; lameness common and severe; recovery or death. In cattle, edema of lips and tongue; hyperemia of oral mucosa; multiple hemorrhages in skin, lips, mucous membrane of the lips, tongue, dental pad, buccal cavity, small intestine, myocardium, epicardium, and endocardium, less frequently in the trachea, nasal cavity, bladder, urethra, pulmonary artery, and pleura, localized necrotic areas followed by ulceration on lips, gums, the dental pad, tongue, mucous membrane of the rumen, pylorus of the stomach, and the external nares; scattered skin lesions with reddening, slight exudation, crusting, sloughing of crusts and hair together,

least 2 weeks at 0° C in virulent blood, less than 2 days in hides dried in direct sunlight, 3 days in contaminated wool, as long as 12 days in meat; is inactivated by glycerine, bile, chloroform, formalin, and 2 per cent phenol, is virulent at least 25 days in body of leech, *Hirudo boaytoni* Wharton (*HIRUDIDAE*), fed on sick animal.

Literature: Boynton, Philippine Agr. Rev., 10, 1917, 410-433, Daubney, Jour. Comp Path and Therap., 41, 1928, 228-248, 263-297, Hornby, *ibid*, 41, 1928, 17-24; Pfaff, Onderstepoort Jour. Vet. Sci and Anim. Indust., 11, 1938, 263-330; 15, 1940, 175-184; Weston, Jour. Am. Vet. Med. Assoc., 66 (N. S. 19), 1921, 337-350.

3 *Tortor equorum* spec. nov. From Latin *equus*, horse

Common names Horse-sickness virus, African horse sickness virus, virus of pestis equorum, virus of perdesiekte, virus of South African Pferdesterbe.

Hosts *EQUIDAE*—*Equus caballus* L., horse, perhaps *E. asinus* L., donkey. Experimentally, also *CAVIDAE*—*Canis familiaris* L., dog. *CAVIIDAE*—*Cavia porcellus* (L.), guinea pig. *MURIDAE*—*Rattus norvegicus* (Erxleben), wild and albino rat, mouse, *Angora* goat, *Mastomys coucha*, multimammate mouse, *Tetra lobengula*, gerbille, chick embryo (but no virus in hatched chick). Mule and zebra relatively resistant.

Insusceptible species. *HOMINIDAE*—*Homo sapiens* L., man. *LEPORIDAE*—*Myxolagus cuniculus* (L.), rabbit (no observed disease).

Geographical distribution Africa, especially in coastal regions and river valleys.

Induced disease. In the horse, four types of disease are recognized. Horse-sickness fever, prodromal period 3 to 28 days, rise of body temperature to 103° F in 1 to 3 days, with return to normal temperature in another day or two, sometimes loss of appetite, redness of conjunctiva, labored breathing, and ac-

celerated pulse; recovery prompt. Diklopp or acute pulmonary horse-sickness, prodromal period of 3 to 5 days, severe dyspnea, fever, coughing, frothing at nostrils, fever to 106° F, breathing rate to 60 a minute, nostrils dilated, head and neck extended, ears drooping, sweating, progressive weakness; often fatal. Diklopp, or cardiac form of horse-sickness, prodromal period 5 to 21 days, fever develops slowly, lasts long; edematous swellings of head and neck, symptoms of cardiac dyspnea, sometimes blood spots on conjunctiva, mucous membranes of mouth and tongue bluish, restlessness; sometimes fatal outcome. Mixed form of horse-sickness, combining features of pulmonary and cardiac types. Horses recovering from natural infections are known as "salted" and possess heightened resistance to the disease.

Transmission. Not by contact. Mosquitoes and biting flies have been suspected as vectors. Experimentally, by intravenous or subcutaneous injection.

Serological relationships. Serologically distinguishable strains exist.

Immunological relationships. Immunity to homologous strain complete after an attack (horse then known as "salted" for that strain), but immunity to heterologous strains incomplete. Antibodies absent from young at birth but as high in titer as in dam within 30 hours, presumably from colostrum milk; declining gradually over a period of about 6 months.

Thermal inactivation. At 57.5 to 60° C in 10 minutes.

Filterability. Passes Berkefeld, Chamberland F, and Seitz EK filters.

Other properties. Viable dry at least 15 months. Stable in alkaline solutions (to pH 10), unstable in acid (beyond pH 6.0). Serum saline solutions preferable to saline solutions for storage. Particle diameter determined as 40 to 60 millimicrons (mean 50 millimicrons) by filtration methods, 45.4 millimicrons by centrifuging. Density 1.25 gm per ml, isoelectric point at pH 4.8.

and seek shade, drooping of wings and tail; eyes closed or partly closed; some dyspnea; in some cases, edema of head and neck; in late stages, sometimes cyanosis of comb and skin; staggering, twitching, or spasms; fever may disappear and temperature become subnormal before death; recovery in about 30 per cent of all cases; linear and punctiform hemorrhages throughout body.

**Transmission:** Method of natural transmission unknown. The fowl louse, *Gonioides dissimilis* (*PHILOPTERIDAE*), has been suspected as vector (Maggiore and Tombolato, Rendiconti, Accademia delle Scienze dell'Istituto di Bologna, n.s. 27, 1923, 200-203). Experimentally, by subcutaneous, intramuscular, and intravenous injection.

**Serological relationships:** Specific neutralizing antiserum does not react with influenza virus. No reaction of fowl-plague virus with antisera specific for canine distemper, influenza, or Rift Valley fever viruses.

**Thermal inactivation:** At 55° C in 1 hour in whole blood or brain.

**Filterability:** Passes membrane of average pore diameter 150, not 100, not ordinarily 125, millimicrons. Passes Berkefeld and Chamberland filters.

**Other properties:** Particle diameter estimated by filtration as 60 to 90 millimicrons; by centrifugation, as 120 to 130 millimicrons. Viable after exposure in 1:10,000 dilution for 10 minutes, in 2 mm layer of 1:50,000 methylene blue, 15 cm from a 300 candle-power filament lamp. Withstands drying. Precipitates from salt-free solutions or in presence of half-saturated ammonium sulphate solutions; virus held to be of globulin nature by Mrowka, *Cent. f. Bakt., I Abt., Orig.*, 67, 1912, 249-263.

**Strains:** Variant strains have been produced by intracerebral passage in brains of canaries and mice.

**Literature:** Bechhold and Schlesinger, *Biochem. Ztschr.*, 236, 1931, 397-414; *Ztschr. Hyg. Infektionskr.*, 112, 1931,

668-679; Burnet and Ferry, *Brit. Jour. Exp. Path.*, 15, 1934, 56-64; Centanni, *Cent. f. Bakt., I Abt., Orig.*, 21, 1902, 145-152, 182-201; Elford and Todd, *Brit. Jour. Exp. Path.*, 14, 1933, 240-246; Findlay and Mackenzie, *ibid.*, 18, 1937, 146-155, 258-264; Findlay et al., *Jour. Path. and Bact.*, 45, 1937, 589-596; Lépine *Compt. rend. Soc. Biol., Paris*, 121, 1936, 509-510; Mackenzie and Findlay, *Brit. Jour. Exp. Path.*, 18, 1937, 138-145; Nieschulz and Bos, *Cent. f. Bakt., I Abt., Orig.*, 131, 1934, 1-6; Plotz and Haber, *Compt. rend. Soc. Biol., Paris*, 125, 1937, 339-340.

8. *Tortor furens spec. nov.* From Latin *furere*, to rage.

**Common name:** Newcastle-disease virus.

**Hosts:** *PHASIANIDAE*—*Gallus gallus* (L.), domestic chicken. *HOMINIDAE*—*Homo sapiens* L., man (by laboratory accident). Experimentally, also pigeon; chick embryo (with primary lesions and cytoplasmic inclusions in chorioallantoic membrane).

**Geographical distribution:** England, probably also East Indies, Korea, Japan, India, Australia.

**Induced disease:** In chicken, acute, febrile, highly contagious, usually fatal disease resembling fowl plague; loss of appetite, crouching attitude, half closed eyes, rapid respirations, watery yellowish-white diarrhea with nay, rating odor; death usually between 6th and 8th day. In man, accidentally infected in laboratory by virus sprayed into eye, virus recoverable from temporarily inflamed eye, recovery in 8 days with gradual increase of specific antibodies in blood.

**Transmission:** By contact between healthy and diseased birds.

**Serological relationships:** Antiserum effective in neutralizing homologous virus.

**Immunological relationships:** Chickens immune to infection by fowl-plague virus are susceptible to infection by this virus.

mucoid or mucopurulent discharge from nostrils; prognosis favorable in mild cases, but disease occasionally terminates with death.

Transmission: Not by contact; arthropod vector suspected.

Other properties: Infective particle calculated to be 87 to 105 millimicrons in diameter by sedimentation studies, 100 to 132 millimicrons in diameter by ultrafiltration.

Literature: Bekker et al., *Onderstepoort Jour. Vet. Sci. and Anim. Indust.*, 2, 1934, 303-307; De Kock et al., *ibid.*, 8, 1937, 129-180; Henning, in Henning, M. W., *Animal Diseases in South Africa*, Central News Agency, Ltd., South Africa, 1932, vol. 2, chapter 27, pages 503-515; Mason and Neitz, *Onderstepoort Jour. Vet. Sci. and Anim. Indust.*, 15, 1940, 149-157; Nieschulz et al., *ibid.*, 2, 1934, 509-562; Polson, *Nature*, 148, 1941, 593-594.

6. *Tortor felis spec. nov.* From Latin *felis*, cat.

Common names. Panleucopenia virus, infectious feline agranulocytosis virus, infectious aleu ocytosis virus, feline enteritis virus.

Host: FELIDAE—*Felis catus* L., domestic cat.

Insusceptible species White mouse, guinea pig, domestic rabbit, ferret, *Citellus richardsoni* (Sabine), ground squirrel.

Geographical distribution United States, Germany.

Induced disease In cat, variable effects, some individuals little affected, others listless, recumbent, refusing food, showing some vomiting, diarrhea, nasal and ocular discharges, often death, after a few minutes of fibrillary twitching and terminal clonic convulsions, before there is much loss of weight, sometimes recovery with return of appetite. Profound leucopenia and marked relative lymphocytosis without thrombopenia or appreciable anemia; proliferation of reticulo-endothelial cells of lymph nodes and

spleen; intranuclear inclusion in cells of gastro-intestinal mucosa, spleen, lymph nodes, bone marrow, and bronchial mucosa.

Transmission: Perhaps by nasal droplets or contaminated food. No arthropod vector recognized. Experimentally by oral, intragastric, cutaneous, subcutaneous, intraperitoneal, intravenous, and intranasal routes.

Serological relationships: Sera from panleucopenia-immune cats protects against agranulocytosis virus.

Immunological relationships: Cats immune as a result of earlier infection with agranulocytosis virus resist later inoculation with panleucopenia virus. Previous inoculation ineffective if made with hog-cholera virus or fox-encephalitis virus.

Filterability. Passes Berkefeld V, N, and W filters and Seitz EK discs.

Other properties: Remains active in 50 per cent glycerine at least 133 days in tissues; not inactivated by drying while frozen, nor by freezing at about  $-80^{\circ}\text{C}$ .

Literature: Hammon and Enders, *Jour. Exp. Med.*, 69, 1939, 327-352; 70, 1939, 557-564; Kikuth et al., *Cent. f. Bakt.*, I Abt., Orig., 140, 1940, 1-17; Lawrence and Syverton, *Proc. Soc. Exp. Biol. and Med.*, 38, 1938, 914-918, Lawrence et al., *Jour. Exp. Med.*, 77, 1943, 57-64; Am. *Jour. Path.*, 16, 1940, 333-354; Syverton et al., *Jour. Exp. Med.*, 77, 1943, 41-56.

7. *Tortor galli spec. nov.* From Latin *gallus*, cock.

Common names. Fowl-plague virus, fowl-pest virus.

Hosts. Chiefly chicken, turkey, goose. Experimentally, also ferret, rhesus monkey, hedgehog, pigeon, duck, canary, mouse, rat, rabbit. Multiplies in embryonated hen's egg, edema, but no discrete primary lesions in chorioallantoic membrane.

Geographical distribution: Widespread throughout Europe, North and South America, Asia.

Induced disease: In chicken, loss of appetite, tendency to leave companions

## FAMILY V. TRIFURACEAE FAM. NOV.

Viruses of the Infectious Anemia Group, inducing diseases mainly characterized by disturbances in balance of blood cells. There is a single genus.

Genus *Trifur* gen. nov.

With characters of the family. Generic name from Latin *trifur*, arrant thief. The type species is *Trifur equorum* spec. nov.

Key to the species of genus *Trifur*.

## I Affecting horse.

## II. Affecting fowl.

1. *Trifur equorum*.2. *Trifur gallinarum*.

1. *Trifur equorum* spec. nov. From Latin *equus*, horse.

Common name: Equine infectious-anemia virus.

Hosts: *EQUIDAE*—*Equus caballus* L., horse; *E. asinus* L., donkey. *HOMINIDAE*—*Homo sapiens* L., man. Experimentally, also *EQUIDAE*—*Equus asinus* × *E. caballus*, mule. *SUIDAE*—*Sus scrofa* L., swine.

Insusceptible species: *BOVIDAE*—*Bos taurus* L., cattle; *Ovis aries* L., sheep; *Capra hircus* L., goat. *CANIDAE*—*Canis familiaris* L., dog.

Geographical distribution: Europe, Union of South Africa, United States, Canada, Japan; at times in most parts of the world; not Australia.

Induced disease In horse, progressive anemia with eventual death or clinical recovery and retention of virus; disease may be acute, subacute, or chronic; in acute disease, temperature rise to 104 to 105° F. or even 106 to 107° F, remaining high much of the time until death or change to subacute or chronic form; in the acute form of the disease there is dullness, decreased appetite, drooping of head, flexing of limb not supporting weight; sometimes increase in pulse frequency to 70 or even 100 a minute but oftener rates around 50 a minute; conjunctiva sometimes colored orange, with injection of vessels and petechiae, later becoming muddy colored or pale red, membrane edematous; uncertain gait,

trailing of hind feet, prostration, sometimes death; subacute disease milder and with remissions; chronic disease still milder, anemia conspicuous, sometimes death from debility or at end of a febrile attack; blood infective long (3 to 7 years) after clinical recovery; urine infective to horse by mouth. In man, diarrhea alternating with constipation, herpes-like exanthema on abdominal wall, blood sometimes in feces; persistent headache, temperature normal; later, lumbar pains, generalized edema, general debility, loss of flesh, pallor of face and mucosae; filtered blood in 1 ml. amount fatal to horse, inducing infectious anemia; improvement after 2 to 4 years. In swine, experimentally, sometimes no outward and obvious signs of disease but blood abnormal and infective; sometimes severe anemia, fever, prostration, loss of appetite.

Thermal inactivation: At 55 to 60° C in 1 hour.

Filterability: Passes Berkefeld V filter candle.

Other properties: Viable in blood in citrate saline at -2° C for at least a year. Drying does not inactivate in 10 days but does in 1 month.

Literature: DeKock, Union of South Africa, Dept. of Agr., 9th and 10th Reports for 1923, Pretoria 1924, 253-313; Habersang, Monatshefte für prakt. Tierheilk., 30, 1920, 171-176; Kutsche, *ibid.*, 30, 1920, 557-568; Peters, Jour. Am. Vet.

and *vice versa*. Immunization to this virus does not decrease susceptibility to comb or mouth form of fowl pox.

Thermal inactivation: At 60° C in 1 hour; not at 56° C in 30 minutes.

Filterability: Passes Berkefeld, Chamberland L<sub>1</sub>, and Seitz filters.

Other properties: Particle diameter calculated from filtration experiments to

be 80 to 120 millimicrons. Not inactivated in 30 minutes in 1:50,000 methylene blue solution in 2 mm layer 15 cm from a 300 candle-power filament lamp.

Literature: Burnet, Med. Jour. Australia, 30, 1943, 313-314; Burnet and Ferry, Brit. Jour. Exp. Path., 15, 1934, 56-64; Doyle, Jour. Comp. Path. and Therap., 40, 1927, 144-169.

## FAMILY VI. RABULACEAE FAM. NOV.

Viruses of the Mumps Group, characterized in general by a special affinity for tissues of the salivary glands. There is a single genus,

Genus I. *Rabula* gen. nov.

With characters of the family. Generic name from Latin *rabula*, pettifogger. The type species is *Rabula inflans* spec. nov.

Key to species of the genus *Rabula*.

I. Affecting man.

II. Affecting guinea pig.

III. Affecting hamster.

IV. Affecting rat.

V. Affecting mouse.

1. *Rabula inflans*.2. *Rabula levis*.3. *Rabula innocuus*.4. *Rabula exiguus*.5. *Rabula latens*.

1. *Rabula inflans* spec. nov. From Latin *inflare*, to puff up.

Common names. Mumps virus, virus of epidemic parotitis.

L  
P  
Mammalia, . . . . .  
—*Felis catus* L., domestic cat.

Geographical distribution: World-wide.

Induced disease: In man, in order of frequency, parotitis, orchitis, meningo-encephalitis, pancreatitis, or ovaritis; rarely fatal, when parotitis occurs, onset . . . . .

ture; cytoplasmic inclusion bodies affected glands, staining pink, round or oval, 3 to 10 microns in diameter, often vacuolate, usually surrounded by a narrow clear zone in the cytoplasm; blood and uninoculated salivary gland of affected animal not effective sources of virus.

Transmission: Probably by droplets arising directly from infected individuals. Experimentally, by injecting sterile fluids containing virus into Stenson's duct of parotid gland in *Macaca mulatta*.

Serological relationships: A specific complement-fixing antibody occurs in human and monkey convalescent serum and is demonstrable by the use of monkey-gland antigen.

Immunological relationships: Specific immunity induced by attack; passive immunization rarely successful.

Thermal inactivation: At 55° C in 1 hour.

Filterability: Passes Berkefeld V and N filter candles.

Other properties: Viable in 50 per cent glycerine at 2° C at least 5 weeks, in 50 per cent glycerine at 10° C. at least 7 weeks, dried while frozen at least 7 weeks, in frozen saliva at least 3 weeks.

swelling and malaise gradually disappearing within a week or 10 days; there is virus in saliva 48 hours after onset; orchitis, less common, is usually unilateral and may be accompanied by some epididymitis. In rhesus monkey, experimentally, acute, non-suppurative parotitis; focal necrosis in acinar epithelial cells of parotid gland, and secondary inflammation; dissemination of lesions within the gland, enlargement of gland to palpation and pitting edema of jaw 6 to 8 days after inoculation, often with a rise of tempera-

Med. Assoc., 66, 1924, 363-366; Theiler and Kehoe, Union of South Africa, Dept. of Agr., 3rd and 4th Reports of the Director of Veterinary Research, 1915, 215-289.

2. *Trifur gallinarum spec. nov.* From Latin *gallina*, hen.

Common name: Fowl-leucosis virus.

Host: *Gallus gallus* (L.), chicken.

Geographical distribution. United States, England, Europe.

Induced disease In chicken, neurolymphomatosis, with eye lesions (slate gray or bluish color replacing normal bay color of iris), anemia, hemocytoblastosis, lymphoid, erythroid or myeloid types of leucosis; the hemocytoblastosis is followed by infiltration of the central nervous system, peripheral nerves, iris, and many visceral organs by hemocytoblasts and lymphocytes, producing lesions sometimes resembling neoplasms and consisting chiefly of hemocytoblasts (hemocytoblastomata); marrow of radius and ulna becomes hyperplastic; virus in blood plasma, blood cells, emulsions of organs; blood normal in its hydrogen-ion concentration; recovery never complete, some stocks less susceptible than others.

Transmission. By pen contact or contaminated litter. Experimentally by intravenous injection of cell-free filtrates. Not by the mosquitoes, *Culex pipiens* and *Aedes aegypti* (CULICIDAE). Day-old chicks from iritis parents contain the infective agent and show some form of the induced disease in 50 per cent of the progeny if both parents show iritis, in 70 per cent if male is normal, 15 per cent if female is normal.

Serological relationships: Specific neutralizing antibodies are formed in the rabbit as a result of injecting infective materials partly purified by sedimentation in the ultracentrifuge.

Thermal inactivation. At 56° C in 30 minutes.

Filterability: Passes Berkefeld V, N, and W filter candles; 1.5 per cent, but not often 3 per cent, collodion membranes; Seitz asbestos filter.

Other properties: Viable after drying at least 54 days, in glycerine at least 104 days, at 4° C at least 14 days, at -60° C at least 6 months; after freezing and thawing, and after freezing in liquid air. Not viable after 14 days at 37.5° C. Particle diameter between 100 and 400 millimicrons.

Literature: Ellermann and Bang, Cent. f. Bakt., I Abt., Orig., 48, 1908, 4-5, 595-609; Furth, Proc. Soc. Exp. Biol. and Med., 27, 1929, 155-157; Jour. Exp. Med., 65, 1931, 243-267; 65, 1932, 465-478, 495-504; 58, 1933, 253-275; 69, 1934, 501-517; Furth and Miller, *ibid.*, 65, 1932, 479-493; Hall et al., Am. Jour. Vet. Res., 2, 1941, 272-279; Järmai, Arch. wissenschaft. u. prakt. Tierheilk., 62, 1930, 113-131; Johnson, Virginia Agr. Exp. Sta. Tech. Bull. 66, 1934, 1-32; Johnson and Bell, Jour. Inf. Dis., 58, 1936, 342-348; Kabat and Furth, Jour. Exp. Med., 71, 1940, 55-70; 74, 1941, 257-261; Lee and Willeke, Am. Jour. Vet. Res., 2, 1941, 292-294; Lee et al., Jour. Infect. Dis., 61, 1937, 1-20; Pierce, Am. Jour. Path., 18, 1942, 1127-1139; Ratcliffe and Stubbs, Jour. Inf. Dis., 62, 1935, 301-304.

No action on sugars.

Anaerobic, facultative.

Optimum temperature 20 to 25°C.

Habitat: Sea water of Norwegian coast.

55. *Pseudomonas calcis* (Drew) Kellerman and Smith. (*Bacterium calcis* Drew, Yearbook Carnegie Inst. Wash., 11, 1912, 136-144; Kellerman and Smith, Proc. Nat. Acad. Sci., 4, 1914, 400) From Latin *calx* (*calc-*), lime.

Ovoid rods, 1.1 by 1.5 to 3 microns, usually single but may form long chains. Actively motile with one polar flagellum. Gram-negative.

Grows best in sea water or 3 per cent salt media. Deposits  $\text{CaCO}_3$ .

Agar colonies: Circular, with finely irregular outline, granular appearance, elevated, spreading; old colonies having brownish tinge in center.

Gelatin stab: Infundibuliform liquefaction.

Gelatin colonies: Small, with liquefaction.

Broth: Good growth especially in presence of potassium nitrate, peptone or calcium malate.

Acid from glucose, mannite and sucrose but not from lactose.

Nitrates reduced to nitrites and ammonia.

Aerobic, facultative.

Optimum temperature 20 to 28°C.

Habitat: Sea water and marine mud.

Bavendamm (Arch. f. Mikrobiol., 5, 1932, 214) states that *Pseudomonas calcis* is probably synonymous with *Bacterium brandii*, *Bacterium bauri* and *Bacterium feitel* described by Parlandt (Bull. Jard. imp. Bot. St. Petersburg, 11, 1911, 97-105).

56. *Pseudomonas calciprecipitans* Mo-  
lisch. (Cent. f. Bakt., II Abt., 65, 1925, 130.) From Latin, *calx* (*calc-*), lime; *precipito*, to cast down headlong, to precipitate.

Thin rods: 0.5 to 0.8 by 1.5 to 3.6 microns, with rounded ends, often staining

irregularly. Motile, with one polar flagellum. Gram-negative.

Gelatin colonies: Circular, light brown in color (large colonies show  $\text{CaCO}_3$  crystals).

Gelatin stab: Surface growth with filiform growth in depth. Liquefaction starts at bottom.

Agar colonies (sea water). Grayish-white, glistening. In two to three weeks crystals of calcium carbonate form in the agar.

Agar slant: Slight, whitish, surface growth, becoming thick, spreading, glistening, with abundant  $\text{CaCO}_3$  crystals in medium.

Ammonia formed.

Aerobic, facultative.

Optimum temperature 20°C.

Habitat: Sea water.

57. *Pseudomonas ichthyodermis* (Wells) Zobell and Upham. (*Achromobacter ichthyodermis* Wells and Zobell, Proc. Nat. Acad. Sci., 20, 123, 1931; Zobell and Upham, Bull. Scripps Inst. Oceanography, 5, 1944, 246 and 253.) From Greek, *ichthys*, a fish; *derma*, skin.

Small rods, 0.9 to 1.3 by 3 to 5 microns, occurring singly and in pairs. No spores. Encapsulated. Polar flagella. Pleomorphic forms predominate in old cultures. Gram-negative.

Requires sea water following initial isolation. The following differential media are prepared with sea water.

Agar colonies: Glistening, colorless, convex, circular colonies 2 to 4 mm. in diameter.

Agar slants: Abundant, filiform, raised, smooth, opalescent growth.

Gelatin tube: Rapid crateriform liquefaction complete in 5 days at 18°C.

Sea water broth: Turbidity, with pelticle, little granular sediment and no odor.

Milk: No growth. Casein digested when 3 per cent salt is added.

Potato: No growth unless dialyzed in sea water. Then fair growth with no pigment.

Literature: Bloch, Am. Jour. Path., 15, 1937, 939-944; Enders and Cohen, Proc. Soc. Exp. Biol. and Med., 50, 1942, 180-184; Findlay and Clarke, Brit. Jour. Exp. Path., 15, 1934, 309-313; Johnson and Goodpasture, Jour. Exp. Med., 59, 1934, 1-19; Am. Jour. Hyg., 21, 1935, 46-57; 23, 1936, 329-339; Am. Jour. Path., 12, 1936, 495-510.

2. *Rabula levis* spec. nov. From Latin *levis*, trifling.

Common name Guinea-pig salivary-gland virus.

Host. *CAVIIDAE*—*Cavia porcellus* (L.), guinea pig (only known host; fetus more susceptible than post-natal animal, even if from immune mother).

Insusceptible species Rabbit, rat, cat, chicken, pigeon, dog, mouse, monkey (*Macacus rhesus*).

Geographical distribution: United States, England.

Induced disease In guinea pig, submaxillary glands show swollen epithelial cells containing relatively dense acidophilic inclusions of granular material with enlarged nuclei, especially in ducts of the serous portion of the gland, and larger but fewer intracytoplasmic inclusions, experimentally, by intracerebral injection of young guinea pig, prodromal period of about 2 days, then elevation of temperature to 105 or 106° F, a day later, hair raised, animal quiet, subsequently, irritability with tremors and slight convulsive movements, by fifth day, usually prostration, jerking movements, and ensuing death, brain shows no gross lesions but exudate over surface, in meningeal exudate, many cells each containing an acidophilic mass within its nucleus, by subcutaneous injection, virus recoverable after 2 weeks from submaxillary glands, cervical lymph nodes, kidney, and lung, not from blood, liver, or spleen.

Transmission Experimentally, by inoculation of submaxillary gland or by intracerebral or subcutaneous injection of materials from infected glands, with

difficulty from brain to brain. Pilocarpine stimulation increases numbers of inclusions.

Serological relationships: Specific neutralizing antibody is found in blood serum of animals that are carrying virus in their submaxillary glands.

Immunological relationships: Active immunity may be dependent on existence of more or less active lesions.

Thermal inactivation. At 54° C in 1 hour.

Filterability Passes Berkefeld N filter candle.

Other properties: Viable in 50 per cent glycerine at least 11 days.

Strains An unusually virulent strain, killing infected animals whatever the route of injection, has been described but not given a distinctive name (Rosenbusch and Lucas, Am. Jour. Path., 15, 1939, 303-310).

Literature. Andrewes, Brit. Jour. Exp. Path., 11, 1930, 23-31; Cole and Kuttner, Jour. Exp. Med., 44, 1926, 855-873; Hudson and Markham, *ibid.*, 65, 1932, 405-415; Jackson, Jour. Inf. Dis., 26, 1920, 317-350; Kuttner, Jour. Exp. Med., 46, 1927, 935-956; Kuttner and Tung, *ibid.*, 62, 1935, 805-822; Lucas, Am. Jour. Path., 12, 1936, 933-948; Markham, *ibid.*, 14, 1938, 311-322; Markham and Hudson, *ibid.*, 12, 1936, 175-182; Pearson, *ibid.*, 6, 1930, 261-274; Scott, Jour. Exp. Med., 49, 1929, 229-236; Scott and Pruett, Am. Jour. Path., 6, 1930, 53-70.

3 *Rabula innocuus* spec. nov. From Latin *innocuus*, harmless.

Common name Hamster salivary-gland virus.

Host *CRICETIDAE*—*Cricetus griseus* M. L. W., Chinese hamster.

Insusceptible species *MURIDAE*—rat, *Mus musculus* L., white mouse.

Geographical distribution China.

Induced disease In hamster, no obvious disease externally but inclusion bodies in submaxillary glands.

Thermal inactivation: At 56° C in 30 minutes.

Literature: Kuttner and Wang, Jour. Exp. Med., 60, 1934, 773-791.

4. *Rabula exiguus spec. nov.* From Latin *exiguus*, petty.

Common name: Rat salivary-gland virus.

Host: *MURIDAE*—rat.

Insusceptible species: *MURIDAE*—*Mus musculus* L., mouse. *CRICETIDAE*—*Cricetulus griseus* M. Edw., Chinese hamster.

Geographical distribution: China, Canada.

Induced disease: In rat, no obvious disease externally, but intranuclear inclusions in cells of the submaxillary glands.

Literature: Kuttner and Wang, Jour. Exp. Med., 60, 1934, 773-791; Thompson, Jour. Inf. Dis., 60, 1932, 162-170.

5. *Rabula latens spec. nov.* From Latin *latens*, hidden or lurking.

Common name: Mouse salivary-gland virus.

Host: *MURIDAE*—*Mus musculus* L., mouse.

Insusceptible species: *MURIDAE*—rat. *CRICETIDAE*—*Cricetulus griseus* M. Edw., Chinese hamster. *LEPORIDAE*—rabbit. *CAVIIDAE*—*Cavia porcellus* (L.), guinea pig.

Geographical distribution: China, Canada, United States.

Induced disease: In mouse, no obvious disease externally, but inclusion bodies in acinar tissue of serous and mucous portions of submaxillary glands; occasionally also in duct cells or alveolar cells of parotid gland; affected cells hypertrophied. In Swiss white mice, extensive lesions in liver and spleen but emulsions of these organs fail to infect; rare pancreatic lesions.

Transmission: Experimentally, by intraglandular, subcutaneous, intraperitoneal, intratesticular or intracerebral inoculation; inclusion bodies appear in salivary glands irrespective of site of inoculation.

Thermal inactivation: At 60° C in 30 minutes.

Filterability: Passes Berkefeld V filter candle.

Literature: Kuttner and Wang, Jour. Exp. Med., 60, 1934, 773-791; McCordock and Smith, *ibid.*, 63, 1936, 303-310; Thompson, Jour. Inf. Dis., 58, 1936, 59-63

SUPPLEMENT NO. 3

PLEUROPNEUMONIA AND  
PLEUROPNEUMONIA-LIKE ORGANISMS  
(BORRELOMYCETACEAE)

Louis Dienes  
Boston, Mass.  
May, 1943

# THE ORGANISM OF CONTAGIOUS BOVINE PLEURO-PNEUMONIA AND RELATED ORGANISMS\*

## INTRODUCTION

The organism of bovine pleuropneumonia is similar in certain respects to filterable viruses. Both in infected tissue and in cultures, small elements are present which pass through filters that retain bacteria. The organism is not stained well by the usual bacterial stains and can be made visible only by using special methods. Bovine pleuropneumonia and other diseases caused by similar organisms were originally attributed to filterable viruses. These organisms are different from viruses in an important point; namely, they grow on suitable media in the absence of living host cells. The cultures consist of pleomorphic elements, the nature of which has only slowly become apparent. By the studies of Nowak (Ann. Inst. Past., 48, 1929, 1330), Turner (Jour. Path. and Bact., 41, 1935, 1) and Klieneberger and Smiles (Jour. Hyg., 42, 1942, 110), it has been established that the pleomorphic forms are part of a reproductive cycle different from binary fission. The small elements in the cultures swell up into large round forms which reproduce the small elements within their membranes. The morphology of the organism is further complicated by the fact that long branching filaments are present in freshly isolated bovine strains. These break up into granules or parts of the filaments swell up into large round forms. In the judgment of some investigators, these properties, in addition to unusual softness and fragility, exclude the organism of bovine pleuropneumonia and similar organisms from the order of true bacteria. Ledingham (Jour. Path. and Bact., 37, 1933, 393) has classified them with the *Actinomyces*. Later, Turner (Jour. Path. and Bact., 41, 1935, 1) placed them in an independent order, *Borrelomycetales*, while Sabin (Bact. Rev., 5, 1941, 58) has even placed them in an independent class, *Paramyces*.

The observations of the present author give support to the classification of Buchanan (Jour. Bact., 3, 1918, 44) who placed the genus *Asterococcus* Borrel et al. with the organism of bovine pleuropneumonia (*Asterococcus mycoides* Borrel et al.) as type, together with the genus *Haemophilus* Winslow et al. in subtribe *Haemophilinae* Buchanan of the tribe *Bacteriaceae* Trevisan emend Buchanan. In many strains of the pleuropneumonia

\*Common names have been used through Supplement No. 3 (except for *Asterococcus* and *A. mycoides*) as the author believes that a more suitable nomenclature than any thus far proposed should be developed when agreement is reached as to the nature of these organisms. Specific names that have been proposed are given merely as a matter of record. No new names have been introduced.

group, the small forms appear in appropriate preparations as small bipolar stained bacilli. The transformation of the bacilli to round bodies of variable size often occurs in bacterial cultures and is not specific for the pleuropneumonia group. Furthermore, it has been observed in several species of bacteria that they reproduce in the large round forms in a manner similar to that observed in the pleuropneumonia group. Thus the form variation and reproductive processes observed in the pleuropneumonia group are not specific to this group. They represent general bacterial properties and should be included in the definition of the true bacteria.

According to these considerations, the organisms belonging to the pleuropneumonia group are small, Gram-negative bacilli often showing bipolar staining and their distinctive characteristic is the tendency to swell up into round forms and multiply by the reproduction of bacilli in the round forms. Their habitat is in the mucous membranes of animals and man and many of them are pathogenic. They are exacting in their media requirements and usually require fresh animal serum for their growth. These properties indicate a close similarity to the species now included in the genera *Pasteurella* and *Haemophilus*. The pleuropneumonia group might well be classified in the same or a closely related family. It is uncertain whether the strains isolated from earth and sewage should be classified with the strains isolated from animals and men. The soil and sewage strains are less soft, stain more easily and grow abundantly without animal serum. The strains isolated from bacterial cultures are most probably variant forms of the bacteria and should be classified with the parent organisms.

The viruses of psittacosis and lymphogranuloma present similarities to the pleuropneumonia group both in morphology and in their methods of reproduction. This gives added weight to the thought that the pleuropneumonia group represents an intermediary stage in the evolution of the small, Gram-negative bacteria of the mucous membranes into the filterable viruses.

## I. THE PLEUROPNEUMONIA GROUP

(*Borrelomycetaceae* Turner, Jour. Path. and Bact., 41, 1935, 25; *Parasitaceae* Sabin, Bact. Rev., 5, 1941, 58.)

The organisms are soft and fragile. Without special precautions they are often distorted or entirely destroyed in microscopical preparations. The cultures contain pleomorphic elements. Small granules, bacilli, bacillary filaments and round forms varying in size from a few tenths of a micron to 10 microns or more. Autolyzed round forms may coalesce into large empty blebs. The round forms are part of a reproductive cycle. They are produced by the swelling of the bacillary forms and filaments and reproduce granules or filaments by inside segmentation or multiple germination. In freshly isolated bovine strains, the filaments show apparent or true branching and reproduce the small forms by segmentation. The smallest growing units may not be larger than 15 to 23 micron and pass through filters that retain bacteria. On agar, tiny colonies (0.1 to 0.6 mm) develop in great numbers. The colonies invade the agar and after 2 to 5 days growth have an opaque center embedded in the agar and a thin peripheral zone. The surface has a rugged or granular appearance due to the development and autolysis of the large forms. After a few days growth, the cultures usually show pronounced autolysis. The parasitic strains require fresh animal serum for growth. There is a single genus.

Genus I *Asterococcus* Borrel et al

(Borrel, Dujardin-Beaumetz, Jeantet and Jouan, Ann. Inst. Past., 24, 1910, 179; *Coccobacillus* Martzinovski, Ann. Inst. Past., 25, 1911, 91; *Micromyces* Frosch, Arch. f. wissenschaftl. u. prakt. Tierheilk., 49, 1923, 35 and 273, not *Micromyces* Dangeard, Le Botaniste, 1, 1888, 55; *Mycoplasma* Nowak, Ann. Inst. Past., 43, 1929, 1349; *Asteromyces* Wroblewski, Ann. Inst. Past., 47, 1931, 105; *Borrelomyces* Turner, Jour. Path. and Bact., 41, 1935, 25; *Borimyces* Sabin, Bact. Rev., 5, 1941, 57.)

Characters as for the family

The type species is *Asterococcus mycoides* Borrel et al

1. *Asterococcus mycoides* Borrel et al (Le microbe de la péripneumonie, Nocard and Roux, Ann. Inst. Past., 12, 1909, 210; Borrel, Dujardin-Beaumetz, Jeantet and Jouan, Ann. Inst. Past., 24, 1910, 168; *Coccobacillus mycoides peripneumoniae* Martzinovski, Ann. Inst. Past., 25, 1911, 914; *Micromyces peripneumoniae boris contagiosae* Frosch, Arch. f. wissenschaftl. u. prakt. Tierheilk., 49, 1923, 35 and 273; *Mycoplasma peripneumoniae* Nowak, Ann. Inst. Past., 43, 1929, 1530; *Asteromyces peripneumoniae boris* Wroblewski, Ann. Inst. Past., 47, 1931, 91; *Borrelomyces peripneumoniae* Turner, Jour. Path. Bact., 41, 1935, 1; *Borimyces pleuropneumoniae* Sabin, Bact. Rev., 5, 1941, 57.)

Morphology of cells and appearance of

agar cultures correspond with the description given for the group.

Broth cultures are slightly opalescent and, upon shaking, the cultures of fresh strains exhibit silk-like whorls, due to the presence of long chains and filaments. The cultures after prolonged incubation consist of small granules.

Biochemical activity. Old colonies on serum agar develop a brownish color. Freshly isolated strains reduce hemoglobin. Glucose, fructose, mannose, maltose, and dextrin are fermented with the production of acid but no gas. The cultures are bile soluble.

The strains isolated from cattle are homogeneous in serological reactions and distinct from the other members of the group.

**Habitat:** It is the causative agent of contagious bovine pleuropneumonia. The disease can be transferred to sheep, goats and water buffaloes, but not to mice, rats, rabbits or other experimental animals

2 The organism of agalactia of sheep and goats. (Le microbe d'agalaxie contagieuse, Bridé and Donatien, Ann. Inst. Past., 39, 1925, 925; *Anulomyces agalactiae* Wroblewski, Ann. Inst. Past., 47, 1931, 111; *Borrelomyces agalactiae* Turner, Jour. Path. and Bact., 41, 1935, 25; *Capromyces agalactiae* Sabin, Bact. Rev., 5, 1941, 57.)

These organisms are very similar to the former organisms in morphology, appearance of the cultures and growth requirements. Usually the growth is less vigorous, the colonies remain smaller, and the elements of the cultures are more delicate and less easily visible than those of bovine pleuropneumonia. Characteristic crystals develop in the cultures.

Serologically and immunologically this species is distinct from the bovine species.

It is the cause of a systemic disease in sheep and goats with involvement of the joints, eyes, and, in lactating animals, the mammary glands. Other species are not susceptible

3 *Pleuropneumonia-like organisms in dogs.* (*Asterococcus canis*, Types I and II, Schoentensack, Kitasato Arch. Exp. Med., 11, 1904, 227; 13, 1936, 175; *Cano-myces pulmonis* I and II, Sabin, Bact. Rev., 5, 1941, 57.)

Both types produce slight uniform opalescence in broth. Type I grows in granules and coarse colonies and is apparently pathogenic for dogs. Type II grows in somewhat larger granular colonies.

They are serologically distinct from each other and from the other members of the pleuropneumonia group

The connection of these organisms with distemper is not proven.

4. *Pleuropneumonia-like organisms in rats.* *L<sub>3</sub>* (Klieneberger and Stebbins, Jour. Hyg., 37, 1937, 143; Jour. Hyg., 40, 1940, 223; *Murimycetes pulmonis* Sabin, Bact. Rev., 5, 1941, 57.)

*L<sub>4</sub>* (Klieneberger, Jour. Hyg., 38, 1938, 453; *Murimycetes arthritidis* Sabin, loc. cit.)

The pyogenic virus of Woglom and Warren (Jour. Exp. Med., 68, 1938, 513) and *L<sub>1</sub>* of Findlay, MacKenzie, MacCallum and Kleineberger (Lancet, 237, 1939, 7) are identical with *L<sub>4</sub>*. The organisms isolated from infected joints by Beeuwkes and Collier (Jour. Inf. Dis., 70, 1942, 1) and Preston (*ibid.*, 70, 1942, 180) probably are identical with *L<sub>4</sub>* but they were not typed serologically.

The requirements for growth, the appearance of colonies and the morphology are very similar to those of the type strain with the difference that long filaments are not observed either in liquid or solid media.

The strains isolated from rats belong to two serological types. *L<sub>1</sub>* was cultivated from chronic lung abscesses, but the number of strains typed is not sufficient to ascertain that all strains isolated from this source belong to one type. The *L<sub>3</sub>* strains are not pathogenic for rats in artificial infection. They produce sup-puration in mice when they are injected with agar.

*L<sub>4</sub>* which is serologically different from *L<sub>3</sub>* was cultivated from abscesses and spontaneous polyarthritis. It produces polyarthritis both in mice and rats. It is not infectious in monkeys, rabbits and guinea pigs. Both *L<sub>3</sub>* and *L<sub>4</sub>* were recovered from the brains of mice kept in the same room with rats.

According to Klieneberger, *L<sub>1</sub>* usually produces somewhat larger and coarser colonies than *L<sub>4</sub>*; *L<sub>3</sub>* grows in broth in small granules, while *L<sub>4</sub>* produces an opalescent growth.

5 *Pleuropneumonitis*-like organisms in mice. (Sabin, *Science*, 88, 1938, 575, and *Bact. Rev.*, 5, 1941, 1; Findlay, Klieneberger, MacCallum and MacKenzie, *Lancet*, 235, 1938, 1511.) A strain isolated by Sullivan and Dienes (*Proc. Soc. Exp. Biol. and Med.*, 41, 1939, 620) is identical with Type A.

Five groups of strains, distinct serologically, and, to a certain extent, distinct also in their pathological properties, have been isolated from mice. These are types A, B, C, D, and E of Sabin. The strains are closely similar to each other and to the rat strains. It is questionable whether the slight differences in the appearance of the colonies and in the morphology of the cultures are of significance.

Type A (*Musculomyces neurolyticus* Sabin) is usually present in the conjunctiva and was isolated also from the lung and brain. Intracerebral injection of Type A produces in mice a characteristic rolling disease due to a toxin which is also present in broth cultures. Intravenous injection produces a transient polyarthritis without damage to the cartilage or ankylosis. Type A is serologically similar to L of Klieneberger, (*Jour Hyg.*, 40, 1940, 201).

Type B (*Musculomyces arthrotropicus* Sabin) was isolated from the brain and from the nasal mucosa. It produces no rolling disease and no soluble toxin. In mice, intravenous injection usually produces a chronic arthritis often leading to ankylosis.

Types C, D and E (*Musculomyces histotropicus* Sabin) were isolated from the same location as Type B and produce similar arthritic lesions. They are serologically distinct from Type B and from each other (Sabin, *Science*, 90, 1939, 18 and Sabin and Johnson, *Proc. Soc. Exp. Biol. and Med.*, 44, 1940, 569).

L<sub>1</sub> isolated from mice by Findlay et al. (*Trans. Roy. Soc. Trop. Med. Hyg.*, 35, 1939-40, 6) and the strains of Edward (*Jour. Path. and Bact.*, 50, 1940, 409) were

not compared serologically with the types of Sabin.

6 *Pleuropneumonia*-like organisms in man. (Dienes, *Proc. Soc. Exp. Biol. and Med.*, 44, 1940, 468, Beveridge, *Med. Jour. of Australia*, 50, 1943, 479, Klieneberger, *Lancet*, 2, 1945, 46.)

They are present in about 30 per cent of women in the genitals and they were isolated from suppurative processes originating from this source. In men they were found in urethritis, cystitis and chronic prostatitis.

The appearance of the colony, the morphology and growth requirements correspond with the animal strains. The human strains grow less abundantly in serum broth than the animal strains.

One strain was found by Sabin (*Proc. Soc. Exp. Biol. and Med.*, 44, 1940, 569) to be serologically different from the strains isolated from rats and mice. It is not known whether the strains are serologically uniform. There is a slight variation in colony form, in the tendency to grow in filaments, and in the abundance of growth, but the variation between the strains is less than the variation due to slightly different cultural conditions.

Mice and rats are usually not susceptible to infection with the human strains, however, several young mice from a single litter were killed in three to six days by subcutaneous or intraperitoneal injection of one strain.

7 *Pleuropneumonia*-like organisms in chick embryos. (Van Herick and Eaton, *Jour. Bact.*, 60, 1945, 47.)

Organisms have been isolated from chick embryos which conform to the pleuropneumonia group with regard to morphology, the appearance of colonies on agar and filterability. The cultures agglutinated red blood cells from various animals. The relation of this strain to the cocco-bacillary bodies of Nelson (see section II) has not been studied.

## II. ORGANISMS OF UNCERTAIN CLASSIFICATION.

*Similar to the Pleuropneumonia Group.*

1. Coccobacillary bodies of Nelson. (Nelson, Science, 82, 1935, 43; Jour. Exp. Med., 65, 1937, 833; Jour. Exp. Med., 72, 1940, 615.)

the pleuropneumonia-like organisms isolated from mice and rats.

Nelson isolated a small bacillary organism apparently connected with coryza and infectious catarrh from the nasal passages of fowls and from the nasal passages and the middle ear of mice and rats. Their size appeared to be 0.3 to 0.4 micron in microscopical preparations and they passed through a filter with a pore size of 640 millimicrons. They were isolated in tissue cultures but they grow also in the cell-free and heated supernatant fluid. The freshly isolated cultures did not grow on blood or on artificial media; however, after 120 passages in tissue cultures the fowl coryza bodies grew on blood agar slants. On ascitic agar this strain forms colonies very similar to those of the pleuropneumonia group with a dark center surrounded by a thin periphery. The organisms in the top layer are sometimes considerably enlarged, but no web-like structure is produced. The organism is less soft and the individual organisms maintained their form in the preparations as do bacteria, and the tendency to grow into the agar is less pronounced than in the pleuropneumonia group. The organism isolated from rats is more pleomorphic than the others.

The coccobacillary bodies were not studied with methods appropriate to determine whether they belong to the pleuropneumonia group and whether the mouse and rat strains are identical with

2. Filterable organisms from sewage and soil. (Fam. *Saprophytaceae* Sabin, Genus *Sapromyces* Sabin, Bact. Rev., 5, 1941, 59.)

The strains isolated by Laidlaw and Elford (Proc. Roy. Soc. London, B, 120, 1936, 292; *Sapromyces laidlawi* A B and C, Sabin, loc. cit.) and Seiffert (Cent. f. Bakt., I Abt., Orig., 139, 1937, 337) according to Ørskov (Cent. f. Bakt., I Abt., Orig., 141, 1938, 230) and Klieneberger (Jour. Hyg., 40, 1940, 204) are closely similar to the organisms of the pleuropneumonia group. They are filterable, and the smallest reproductive units of those which we have appropriately examined were found to be between .125 and .175 micron. The colonies are similar in appearance to the colonies of the pleuropneumonia group.

The broth cultures consist of granules and round globular elements; the surface layer of agar colonies sometimes swells up into large round forms. They grow without serum, but small amounts of serum accelerate the growth. They grow both at 30° and at 37°C. and remain alive in cultures kept cold for several months. The broth cultures grow abundantly with a strong opalescence or sediment. Serologically the strains are distinct from the other members of the pleuropneumonia group and all but one are more or less similar to each other.

## III. PLEUROPNEUMONIA-LIKE ORGANISMS ISOLATED FROM BACTERIAL CULTURES.

1. Pleuropneumonia-like organisms isolated from *Streptobacillus moniliformis*. L<sub>1</sub> (Klieneberger, Jour. Path. and Bact., 40, 1939, 93; Jour. Hyg., 42, 1942, 485; Dienes, Jour. Inf. Dis., 65, 1939, 24; Jour. Bact., 44, 1942, 37; *Mus-*

*culomyces streptobacilli-moniliformis* Sabin, Bact. Rev., 5, 1941, 57; Heilman, Jour. Inf. Dis., 62, 1941, 32; Brown and Nunemaker, Bull. Johns Hopkins Hosp., 70, 1942, 201.)

Cultures isolated from different strains

Acid from glucose, maltose, sucrose and mannitol but not from lactose or glycerol.

Starch hydrolyzed.

Ammonia liberated from peptone but no hydrogen sulfide produced

Indole formed in tryptophane sea water broth.

Nitrites produced from nitrates

Optimum temperature 20 to 25°C, 36°C incubation will kill recently isolated organisms.

Aerobic, facultative

Source: Isolated from diseased killfish (*Fundulus parvipinnis*)

Habitat: Skin lesions and muscle tissue of infected marine fish.

53. *Pseudomonas nigriciens* White (Scientific Agriculture, 20, 1910, 643) From Latin *niger*, black and *faciens*, making.

Rods: 0.3 to 0.7 by 1 to 5 microns, occurring singly or in pairs, and having rounded ends. Actively motile, with a single polar flagellum Gram-negative

Gelatin stab: Pigmented surface growth after 24 hours Slight crateriform liquefaction changing to sacrate

Agar colonies. Circular, convex, smooth, glistening, entire, 2 to 4 mm in diameter. Slight fluorescence in early stages The medium assumes a brownish color.

Agar slant Growth filiform, smooth, moist, glistening, with blackish pigmentation at 4° and 15°C in 48 hrs, the medium turning brownish Slight fluorescence in early stages

Broth Turbid after 24 hours. After 5 to 6 days a black ring and then a pellicle forms, later a black sediment. Medium turns brown

Litmus milk A black ring appears after 3 days at 15°C followed by a pellicle. Litmus is reduced Alkaline reaction. No coagulation. Digested with a putrid odor.

Indole not formed.

Nitrites not produced from nitrates in 7 days. No gas produced.

Starch is hydrolyzed Natural fats not hydrolyzed.

Alkaline reaction produced in sucrose, maltose, lactose, glucose, mannitol and raffinose broth (pH 8.2). No gas produced

Ammonia produced in peptone broth. Aerobic.

Optimum pH 6.8 to 8.4.

Temperature relations: Minimum 4°C. Optimum 25°C. Maximum 33-35°C

Distinctive characters: No or slow growth in culture media in the absence of salt. Maximum growth and pigmentation appeared with 1.5 and 2.5 per cent salt. Optimum pigmentation occurs at 4° and 15°C

Source: Several cultures isolated from samples of discolored butter.

Habitat: Causes a black to reddish-brown discoloration of print butter. Evidently widely distributed in nature.

59 *Pseudomonas beijerinckii* Hof. (Travaux botaniques néerlandais, 33, 1935, 152.) Named for M. W. Beijerinck, Dutch bacteriologist.

Small rods: Motile with polar flagella.

Gelatin: No liquefaction.

Indole not formed.

Nitrites produced from nitrates by four out of six strains.

Cellulose not decomposed.

Acid from glucose. In yeast-water with 2 per cent glucose and 12 per cent NaCl no gas is produced.

Pigment production: Insoluble purple pigment produced but not in all media; is localized markedly; reduced oxygen tension necessary; optimum pH 8.0; not produced in yeast-water or in peptone-water; produced only when grown in extracts of beans or some other vegetable.

Aerobic.

Source: Six strains isolated from beans preserved with salt.

Habitat: Causes purple discoloration of salted beans.

The strains, like the parent organism, are strictly anaerobic and the cultures have the characteristic odor of the parent strain.

It was observed in slide cultures that the L type of colonies develop from large round forms which were produced in the cultures of the parent organism by gradual swelling of the bacteria.

In cultures of eight pleomorphic strains of *Bacteroides*, the L type of colonies developed in three strains under appropriate conditions. The bacteria swelled into large round bodies in all eight strains. The serological properties of the L strains have not thus far been studied. Neither the parent organisms nor the L type strains had any pathological effect on laboratory animals.

3. Pleuropneumonia-like organisms in a species of *Flavobacterium*. (Dienes, Jour. Bact., 44, 1942, 37.)

Tiny colonies entirely similar in appearance to young L<sub>1</sub> colonies were isolated from the cultures of a species of *Flavobacterium*.

The bacterium when freshly isolated produced two types of colonies on blood agar plate; large colonies consisting of small regular bacilli and tiny colonies in

which the bacteria became pleomorphic and swelled up to form large round bodies. The tiny colonies after 48 hours of incubation became autolyzed, and one or several L type of colonies started to grow under them. These colonies could be transplanted and gave abundant growth for two generations, but always died out in the third.

Bacterial forms were not reproduced either on agar or in broth.

The L type of growth was not pathogenic for mice though the parent organism was highly virulent.

#### 4. Development of tiny colonies in other bacteria.

The development of tiny colonies similar in appearance to young colonies of the pleuropneumonia group has been observed in cultures of *Escherichia coli*, *Haemophilus influenzae*, and *Neisseria gonorrhoea* (Dienes, Jour. Bact., 44, 1942, 37; Proc. Soc. Exp. Biol. and Med., 44, 1940, 476). In all cases preceding their development, the organisms of the parent strains swelled into large round bodies, and in *Escherichia coli* and *Haemophilus influenzae* the development of the L type of colonies from these large forms was observed. Thus far these tiny colonies have not been isolated in pure cultures.

of *Streptobacillus moniliformis* vary considerably in the appearance of the colonies, the tendency to reversion to bacillary form, and the degree of autolysis. The colonies are considerably larger than the colonies of the human or animal pleuropneumonia-like strains; they may reach 1 to 2 mm. Usually a wide peripheral zone is present and development and autolysis of the large bodies produces a coarse appearance in the colonies. Sometimes no peripheral zone develops, the colony is dome-shaped, and the large bodies have no tendency to autolyze. The young colonies (twelve hours incubation) grow into the agar as loose strands of more or less swollen granules. Serum broth cultures grow in small clumps usually adhering to the wall of the test tube.

The cultures consist of small granules, small polar-staining bacilli and diphtheroid like forms which swell to large round forms. In the top layer of fully developed colonies, the well-stained large bodies may be as large as 10 to 20 microns. By vacuolization they transform into empty blebs. By segmentation of their contents, the large forms may reproduce the small bacillary forms. In suitable preparations chromatin bodies are visible both in the small and large forms. The small forms are filterable through Berkfeld candles, the size of the smallest particles has not been exactly determined. The organism is very soft and fragile.

Their growth requirements and biochemical activities are similar to those of *Streptococcus moniliformis*.

Growth occurs on nutrient agar containing animal serum or egg yolk. Sometimes there is a slight growth on boiled blood agar plates without serum. Good growth is obtained in a mineral solution with 0.1 per cent starch. Growth is both aerobic and anaerobic.

The Ia form is more resistant to heat and to aging of the culture than is the streptococcus and it has a remarkable resistance to penicillin to which the fac-

teria are very sensitive. Like the bacillus, *L*<sub>1</sub> produces acid but no gas from glucose, maltose, fructose, salicin, starch, and dextrin. It gives no oxidase test.

Serologically the *L*<sub>1</sub> form is similar to *Streptobacillus moniliformis* and different from the members of the pleuropneumonia group. It has no pathological effect on mice, rats or guinea pigs. It does not produce an infection of the chicken embryo. It can be isolated from freshly isolated strains of *Streptobacillus moniliformis*, from several-day old broth and agar cultures, from broth cultures heated at 56°C. and usually also from 48 hour agar cultures if they are incubated at 23° to 30°C. It is questionable whether the *L*<sub>1</sub> form has been isolated directly from rats.

Klieneberger (Jour. Hyg., 40, 1910, 201) isolated a similar strain from a bacterium similar to *Streptobacillus moniliformis* which caused abscesses in guinea pigs. Whether this bacterium was identical or different from *Streptobacillus moniliformis* was not determined.

2 Pleuropneumonia-like organisms isolated from *Bacteroides funduliformis*. Dienes (Proc Soc Exp. Biol. and Med., 47, 1941, 355) and Dienes and Smith (Jour Bact., 48, 1941, 125) isolated cultures from two strains of *Bacteroides funduliformis* which could be propagated indefinitely and which in morphology and in the appearance of colonies were closely similar to L.

The young colonies consisted of similar strands of granules growing into the medium. The surface of fully developed colonies consisted of large bodies and a honey comb-like structure. The well isolated colonies grew usually to a fairly large size (1 to 2 mm).

Both strains, transplanted every two or three days through several months, failed to reproduce bacteria, although

turns.

60. *Pseudomonas salinaria* Harrison and Kennedy. (Harrison and Kennedy, Trans. Royal Soc. of Canada, 16, 1922, 121; *Serratia salinaria* Bergey et al., Manual, 1st ed., 1923, 93; *Flavobacterium* (*Halobacterium*) *salinarum* Elazari-Volcani, Studies on the Microflora of the Dead Sea, Thesis, Hebrew Univ., Jerusalem, 1940, 59) From Latin, *salinae*, saltworks.

Probable synonym: *Serratia sambhari-anus* Dixit and Vachna, Current Sci., 11, 1942, 107 (see Biol. Abs., 17, 1943, 793). Halophilic growing in 30 per cent salt. From salt lake in India

Occurs as spheres and rods, 2.0 to 3.0 microns in diameter, 1.0 to 1.6 by 3.0 to 15.0 microns, occurring singly, as ovoid, amoeboid, clavate, cuneate, truncate, spindle, club, pear-shape, and irregular forms. Motile, frequently with a flagellum at each pole. Gram-negative.

Does not grow on ordinary culture media. Grows well on salted fish.

Codfish agar (16 to 30 per cent salt): Growth slow, smooth, raised, coarsely granular, entire, pale pink to scarlet (Ridgway chart).

No acid from carbohydrate media.

Indole not formed.

Nitrites not produced from nitrates.

Aerobic, facultative

Optimum temperature 42°C.

Source: Isolated from cured codfish (Harrison and Kennedy, *loc. cit.*) Isolated from salted fish by Browne (Absts. Bact., 6, 1922, 25 and Proc. Soc. Exper. Biol. and Med., 19, 1922, 321) who regarded this pleomorphic bacterium as two organisms—*Sprochaeta halophilica* and *Bacterium halophilica*

Habitat: Produces reddening of dried codfish and causes rusty herring. In sea salt, and salt ponds containing not less than 16 per cent salt

61. *Pseudomonas cutirubra* Lochhead. (*Serratia cutirubra* Lochhead, Can. Jour.

of Research, 10, 1934, 275; *Bacterium cutirubrum* Lochhead, Jour. Bact., 27, 1934, 62; *ibid.*, 45, 1943, 575; *Flavobacterium* (*Halobacterium cutirubrum* Elazari-Volcani, *loc. cit.*, 59.) From Latin, *cutis*, skin, hide; *ruber*, red

Occurs as rods and spheres. Spheres 1 to 1.5 microns in diameter. Rods 1.5 to 8.0 by 0.7-1.4 microns. Rod forms motile with single polar flagellum. Coccoid forms motile when young. Gram-negative.

No growth on ordinary media.

Milk agar (20 per cent salt to saturation; optimum 23-32 per cent): Colonies 3-4 mm. in diameter, round and slightly convex. Pink to rose dorée (Ridgway chart).

Milk agar slants: Growth filiform, slightly spreading, rather flat with smooth, glistening surface and membranous consistency. Proteolytic action.

Liquid media: No or slight growth.

Gelatin (salt): Pronounced liquefaction.

Indole not formed, Lochhead (*loc. cit.*), Faint test, Gibbons (Jour. Biol. Board Canada, 3, 1936, 75).

Nitrites not produced from nitrates.

Diastatic action negative.

No carbohydrate fermentation.

Aerobic, obligate.

Optimum temperature 37°C.

Halophilic.

Source: Isolated from salted hides.

Habitat: Sea water and sea salt.

62. *Pseudomonas harveyi* Johnson *comb. nov.* (*Achromobacter harveyi* Johnson and Shunk, Jour. Bact., 31, 1936, 587.) Named for E. N. Harvey, who studied luminous bacteria.

Rods 0.5 to 1.0 by 1.2 to 2.5 microns, occurring singly or in pairs, with rounded ends. Occasionally slightly curved; ends occasionally slightly pointed. Non-spore-forming. Capsules absent. Motile with a single polar flagellum, 2 to 3 times the length of the cell. Gram-negative.

    - Anulomyces*, 1292
  - Glanders
    - Malleomyces*, 555

Sea water gelatin colonies After 24 hours at 20°C, circular, about 1.5 mm in diameter or larger, margin slightly undulate, sunken due to the beginning of liquefaction, interior somewhat zonate, colonies surrounded by a halo of numerous small secondary colonies, circular and finely granular. In crowded plates a large number of gas bubbles are formed. Luminescent.

Sea water gelatin stab Rapid saccate liquefaction complete in 5 days at 22°C. Abundant flocculent sediment.

Sea water agar colonies Mostly very large, 6 to 8 cm. in diameter in 24 hours, flat, highly iridescent, circular with undulate margin, or composed of narrow and close or wide filamentous growth. Occasionally small colonies appear that are circular, with entire or slightly undulate margin, often producing irregular secondary growth, surface always smooth. Luminescent.

Sea water agar slant Growth abundant, spreading, grayish viscous, homogeneous, iridescent, the medium becoming rapidly alkaline when inoculated at an initial pH of 7.0. With fish decoctions added to the medium, luminescence is much brighter and growth becomes brownish after several days.

Growth on autoclaved fish Abundant, smooth, glistening, yellowish, becoming dirty brown after several days. Mild putrefactive odor. Luminescence very brilliant.

Sea water containing 0.2 per cent peptone: Abundant uniform turbidity, thin pellicle, sediment accumulating over a period of several days. Luminescence at surface only unless the tube is shaken.

Milk, with or without the addition of 2.8 per cent salt. No growth.

Potato plugs resting on cotton saturated with sea water: Growth slight, somewhat spreading, slightly brownish. Luminous indole is formed (Gore's method).

Nitrites are produced from nitrates.

Ammonia is produced in peptone media (Hansen method).

Fixed acid from glucose, fructose, mannose, galactose, sucrose, maltose, mannitol, dextrin, glycogen, trehalose, cellobiose; slowly from salicin. Non-fixed acid from melezitose, slight acid from sorbitol, disappearing in 24 hours. No acid from glycerol, xylose, arabinose, dulcitol, inositol, adonitol, erythritol, arabitol, lactose, raffinose, rhamnose, fucose or alpha methyl glucoside.

Starch agar. Wide zone of hydrolysis.

Hydrogen sulfide is produced (Zobell and Fantham method).

Temperature relations Optimum 35° to 39°C. Abundant growth at 22° to 25°C. Optimum luminescence at 20° to 40°C.

Not pathogenic for white rats or amphipods.

Aerobic, facultative anaerobic.

Source Isolated from a dead amphipod (*Talorchestia* sp.) at Woods Hole, Massachusetts.

Habitat Sea water.

63 *Pseudomonas phosphorescens* (Fischer) Bergey et al. (*Bacillus phosphorescens* Fischer, Zeitschr. f. Hyg., 2, 1887, 58; *Photobacterium indicum* Beijerinck, Arch. Néerl. d. Sci. Exactes, 23, 1889, 401; *Bacterium phosphorescens* Lehmann, Cent. f. Bakt., 5, 1889, 785; not *Bacterium phosphorescens* Fischer, Cent. f. Bakt., 3, 1888, 107; Bergey et al., Manual, 3rd ed., 1930, 177). From Greek *phosphorēō*, to bear or bring light.

See page 699 for additional synonyms.

Description taken from Fischer (loc. cit.).

Small, thick rods 2 to 3 times as long as wide, with rounded ends. Motile. Stain lightly with aniline dyes.

Gelatin colonies After 36 hours, small, circular, gray-white, punctiform. Liquefaction Bluish to green phosphorescence in 4 to 5 days.

Blood serum: Gray-white, slimy growth.

Potato. Thin white layer in 2 to 3 days.

Cooked fish: Abundant growth. Entire surface covered with a gray-white, slimy growth. Bluish-white phosphorescence.

Alkaline broth: Slight turbidity in 24 hours. Pellicle in 3 days.

Acid broth: No turbidity. No phosphorescence.

Milk: No growth.

No gas formed.

Not pathogenic for laboratory animals.

Aerobic.

Optimum temperature 20° to 30°C.

Source: From sea water of the West Indies.

Habitat. Sea water.

64. *Pseudomonas pierantonii* (Zirpolo) Bergey et al. (*Micrococcus pierantonii* Zirpolo, Boll. del. Società dei Natural. in Napoli, 31, 1918, 75; *Cocco-bacillus pierantonii* Meissner, Cent. f. Bakt., II Abt., 67, 1926, 204; Bergey et al., Manual, 3rd ed., 1930, 176) Named for Pierantoni, an Italian.

Oval rods: 0.8 by 1.0 to 2.0 microns. Polymorphic rods, sometimes vacuolated. Motile. Gram-negative.

Gelatin colonies: Circular, luminous.

Gelatin stab. Not liquefied.

Sepia agar colonies: Circular, white, convex, smooth, serrate edge. Intense greenish luminescence.

Egg-glycerol agar slant: Yellowish-green, luminous streak.

Broth: Turbid.

Indole not formed.

Acid from glucose and maltose, some strains also produce acid from lactose and sucrose.

Best growth in alkaline media.

Aerobic.

Optimum temperature 33°C.

Source Isolated from the photogenic organ of the cephalopod *Rondeletia minor*.

\*65. *Pseudomonas martyniae* (Elliott) Stapp. (*Bacterium martyniae* Elliott, Jour. Agr. Res., 29, 1924, 490; Stapp, in Sorauer, Handbuch der Pflanzenkr., 2, 5 Auf., 1928, 278; *Phytomonas martyniae* Bergey et al., Manual, 3rd ed., 1930, 262.) From M. L. *Martynia*, a generic name.

Rods: 0.50 to 1.63 microns. Capsules. Chains. Motile with one to several bipolar flagella. Gram-negative.

Green fluorescent pigment produced.

Gelatin: Liquefied.

Beef agar colonies: White, round, smooth, glistening, raised.

Broth: Clouding in bands. Thin pellicle. Small crystals.

Milk: Soft acid curd with peptonization.

Nitrites produced from nitrates after 2 weeks.

Indole not produced.

Hydrogen sulfide production slight.

Acid but not gas from glucose, galactose, arabinose and sucrose. No acid from rhamnose, lactose, maltose, raffinose, mannitol and glycerol.

Starch hydrolysis none or feeble.

Optimum temperature 26°C. Maximum 37°C. Minimum 1.5°C.

Optimum pH 6.0 to 6.7. pH range 5.4 to 8.9.

Aerobic.

Source: Isolated from diseased leaves of the unicorn plant from Kansas.

Habitat: Pathogenic on *Martynia louisiana*.

66. *Pseudomonas striafaciens* (Elliott) Burkholder. (*Bacterium striafaciens* Elliott, Jour. Agr. Res., 35, 1927, 823; *Phytomonas striafaciens* Bergey et al., Manual, 3rd ed., 1930, 268; Burkholder, Phytopath., 32, 1942, 601.) From L. *stria*, stripe; *faciens*, making,

\* The section covering the pseudomonads that cause plant diseases has been revised by Prof. Walter H. Burkholder, Cornell Univ., Ithaca, New York, April, 1943.

referring to the type of lesion caused on the blades of oats.

Rods: 0.66 by 1.76 microns. Motile with one to several flagella. Capsules Gram-negative.

Green fluorescent pigment produced  
Gelatin: Liquefied.

Beef-peptone agar colonies White, raised, margins entire or slightly undulating

Broth: Clouding in layers Ring and slight pellicle

Milk: Alkaline, sometimes a soft curd which digests or clears

Slight production of nitrites from nitrates.

Indole not produced

Acid but not gas from glucose, fructose and sucrose. No acid from lactose, maltose, glycerol and mannitol

Starch: Hydrolysis slight.

Optimum temperature 22°C

Optimum pH 6.5 to 7.0

Aerobic.

Distinctive characters Differs from *Pseudomonas coronafaciens* in that the cells are somewhat smaller and the pathogen produces a streak on oat blades instead of a halo spot

Source: Forty cultures isolated from oats gathered in various parts of America

Habitat: Pathogenic on cultivated oats, and to a slight degree, on barley.

67. *Pseudomonas tomato* (Okabe) *comb. nov.* (*Bacterium tomato* Okabe, Jour Soc Trop Agr Formosa, 5, 1933, 32, *Phytomonas tomato* Magrou, in Hauduroy et al, Dict. d. Bact. Path., Paris, 1937, 422) Named for the host plant, tomato

Probable synonym: *Bacterium punctulans* Bryan, Phytopath., 23, 1933, 897

Rods: 0.60 to 0.97 by 1.8 to 6.8 microns  
Motile with 1 to 3 polar flagella Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Slow liquefaction.

Beef-extract agar colonies White, circular, flat and glistening.

Broth: Turbid in 24 hours Pellicle

Milk: Becomes alkaline and clears.

Nitrites are usually produced from nitrates

Indole not produced

No H<sub>2</sub>S produced.

Acid but not gas from glucose, sucrose and lactose No acid from maltose and glycerol.

Starch hydrolysis feeble.

Slight growth in 3 per cent salt

Optimum temperature 20° to 25°C.  
Maximum 33°C.

Aerobic.

Source: Isolated from diseased tomato leaves

Habitat Pathogenic on tomato, *Lycopersicon esculentum*

68 *Pseudomonas aceris* (Ark) Burkholder (*Phytomonas aceris* Ark, Phytopath., 29, 1939, 969, Burkholder, Phytopath., 32, 1942, 601) From Latin *acer*, maple, M L. *Acer*, generic name.

Rods 0.3 to 0.8 by 0.8 to 2.5 microns.  
Motile with 1 to 2 polar flagella. Gram-negative

Green fluorescent pigment produced

Gelatin: Liquefied

Beef-extract-peptone agar. Colonies are grayish-white Appearing in 24 hours.

Broth Turbid.

Milk Clearing with no coagulation

Nitrites not produced from nitrates

Indole not produced

Hydrogen sulfide not produced.

Acid from glucose, fructose, galactose, arabinose, xylose, sucrose, maltose, lactose, raffinose, mannitol, glycerol and dulcitol

Slight growth in broth plus 6 per cent salt (Burkholder)

Temperature. 13° to 31°C.

Source From diseased leaves of the large leaf maple, *Acer macrophyllum*

Habitat: Causes a disease of *Acer spp*

69 *Pseudomonas angulata* (Fromme and Murray) Holland (*Bacterium angulatum* Fromme and Murray, Jour Agr. Res., 16, 1919, 219; Holland, Jour. Bact., 5, 1920, 221; *Phytomonas angulata* Bergey

*Clostridium*, 796, 810  
*Lactobacillus*, 354  
*Streptococcus*, 331  
 —, mouth  
*Streptococcus*, 331  
 —, mucous membrane  
*Bacteroides*, 574  
*Streptococcus*, 242, 243, 244  
 —, natural cavities of mammals  
*Gaffky*, 284  
 —, saliva  
*Streptococcus*, 304  
 Gerbilles, erythrocytes  
*Hemobartonella*, 1108  
 Ground hogs  
*Pasteurella*, 551  
 Hamsters, erythrocytes  
*Grahamella*, 1110, 1111  
*Haemobartonella*, 1104  
 Hamsters, Chinese  
 Erythrocytes  
*Haemobartonella*, 1108  
 Jerboa, erythrocytes  
*Haemobartonella*, 1108  
 Laboratory animals  
*Streptococcus*, 317  
 Lemmings  
*Pasteurella*, 551  
 Moles, erythrocytes  
*Grahamella*, 1109  
 Monkeys  
*Bartonella*, 1108  
*Spirochaeta*, 1068  
 —, blood  
*Rickettsia*, 1088  
*Spirillum*, 1065  
 —, erythrocytes  
*Grahamella*, 1111  
*Haemobartonella*, 1104  
 —, infected with yellow fever virus  
*Corynebacterium*, 404  
 —, trachoma  
*Chlamydozoon*, 1114  
 Musk rats  
*Pasteurella*, 551  
 Opossum, blood  
*Spirochaeta*, 1066  
 —, erythrocytes  
*Haemobartonella*, 1108  
 Otter, blood  
*Spirochaeta*, 1067  
 Primates, lower  
*Salmonella*, 502  
 Rodents  
*Pasteurella*, 549, 551  
*Salmonella*, 517, 527  
*Spirochaeta*, 1068  
*Streptococcus*, 310  
 —, blood  
*Borrelia*, 1064  
 Shrew mouse  
*Spirochaeta*, 1066  
 Shrew, short tailed

## Insects (continued)

et al., Manual, 3rd ed., 1930, 267.) From *L. angulatus*, referring to the type of lesion produced on the tobacco leaf.

Description taken from Clara (Cornell Agr. Exp. Sta. Mem. 159, 1934, 24).

Rods. 0.75 to 1.5 by 1.5 to 3.0 microns. Motile by 1 to 6 polar flagella. Gram-negative.

Gelatin: Liquefaction.

Green fluorescent pigment produced.

Beef-extract agar colonies: Dull white, circular, raised, smooth and glistening.

Broth: Turbid in 36 hours and greenish.

Milk: Alkaline.

Nitrites not produced from nitrates.

Indole not produced.

No  $H_2S$  produced.

Lipolytic action negative (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid but not gas from glucose, galactose, fructose, mannose, arabinose, xylose, sucrose and mannitol. Alkaline reaction from salts of citric, malic, succinic and tartaric acid. Rhamnose, maltose, lactose, raffinose, glycerol, salicin, and acetic, lactic and formic acids are not fermented.

Starch not hydrolyzed.

Slight growth in broth plus 5 to 6 per cent salt (Burkholder).

Facultative anaerobe.

Distinctive characters: Braun (*Phytopath.*, 27, 1937, 283) considers this species to be identical in culture with *Pseudomonas tabaci*, but they differ in the type of disease they produce.

Sources: Isolated by Fromme and Murray from small angular leaf spots on tobacco.

Pathology: Causes the angular leaf spot on tobacco (*Nicotiana tabacum*).

*Pseudomonas aptata* (Brown and Stevens). (*Bacterium aptatum* Brown and Jamieson, *Jour. Agr. Res.*, 1, 1906; *Phytoplasma aptata* Bergey et al., Manual, 1st ed., 1923, 184; Stevens, *Disease Fungi*, New York, 1925, 106.) From Latin *aptatus* adapted.

Rods. 0.6 to 1.2 microns. Motile with 6 to 12 flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction.

Agar slants: Moderate growth along streak, filiform, whitish, glistening.

Broth: Turbid: A pellicle formed.

Milk: Becomes alkaline and clears.

Nitrites not produced from nitrates.

Indole not produced in 10 days. Slight amount found later.

No  $H_2S$  produced.

Acid from glucose, galactose and sucrose. No acid from lactose, maltose and mannitol (Paine and Banfoot, *Ann. Appl. Biol.*, 11, 1924, 312).

Starch not hydrolyzed.

Slight growth in broth plus 7 per cent salt (Burkholder).

Optimum temperature 27° to 28°C. Maximum 34° to 35°C. Minimum below 1°C.

Aerobic.

Source: Isolated from diseased nasturtium leaves from Virginia and diseased beet leaves from Utah.

Habitat: Pathogenic on sugar beets, nasturtiums, and lettuce.

71. *Pseudomonas primulae* (Ark and Gardner) Starr and Burkholder. (*Phytoplasma primulae* Ark and Gardner, *Phytopath.*, 26, 1936, 1053; Starr and Burkholder, *Phytopath.*, 32, 1942, 601.) From *L. primulus*, first; M.L. *Primula*, a generic name.

Rods: 0.51 to 0.73 by 1.0 to 3.16 microns. Motile with a polar flagellum. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction.

Agar colonies: Round, convex, smooth, glistening, yellowish.

Milk: Coagulated.

Nitrites not produced from nitrates.

Indole not produced. No  $H_2S$  produced.

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid but not gas from glucose, lactose, sucrose, maltose, galactose, arabinose,

Plant Diseases (*continued*)Cucumber (*continued*)

Wilt, 468

## Cumin

Blighted, 121

*Dactylis glomerata*

Slimy heads, 394

## Dahlia

Tuber and stem rot, 473

## Delphinium

Black spot on leaves, 115

## Douglas fir

Galls on, 231

## Dill

Blighted, 121

## Egg Plant

Soft rot, 471, 474

## Elms, 279

Dark discoloration of wood, 142

Wet wood, 472

## English walnut

Black spot of leaves and nut, 159

*Eugenia latifolia*

Witches'-broom, 399

## Fig

Blight, 640

## Filbert trees, 157, 640

## Flax

Leaf stripes, 166

## Foxtail, 142

## French endive

Rot, 125, 131

## Gardenias, 696

General, 89, 341

Leaf spot, 136

## Geranium

Fasciated growth, 395

Galls on, 228, 229, 230, 231

General, 167

Leaf spot, 160

## Giant cactus

Rot, 468

## Ginger

Sprout rot, 171

## Ginseng

Root rot, 131, 477

## Glabolus, 118, 478

Gummy lesions on leaves, 168

Tubers, corn rot, 130

## Grapes, 145, 466, 478, 639, 753

## Grapevines, 276

## Grasses, 142

## Hazelnut, Turkish

Leaves and stems of, 139

## Heron's bill

Leaf spot, 122

## Horse-radish, 164

Black rot of, 155, 156

Root rot, 477

## Hyacinth

Soft rot, 471

Yellow rot, 152

## Iris, 118, 140, 147

Blight on leaves, 639

Brown leaf spot, 140

Soft rot, 177, 471

## Italian millet

Brown stripe, 126

## Ivy

Leaves, 160

## Ivy, Japanese

Black spot on leaves, 134

## Johnson's grass

Leaf stripe, 171

## Jute

Water-soaked to brown spots on leaves, 164

## Konjac, 171

## Kudzu vine

Halo blight, 119

## Larkspur

Bacterial blight, 696

Rot, 131

## Lentils

Root rot, 141

## Lettuce, 151, 158, 746

Leaves, 114, 115

Marginal lesions, 126

Root disease, 129

Rosette disease, 129

Rot, 125, 131

## Lettuce, wild, 151

## Lilac, 120

## Lily

Brown spots on bulbs, 477

## Loquat

Bud rot, 141

## Lorag

Spot on leaves, 141

## Lucerne

Root rot, 141

  - Leaves, sheaths and culms, 169

glycerol, dulcitol and mannitol. Starch not hydrolyzed.

Growth in broth plus 5 per cent salt.  
Optimum temperature 19° to 22°C.  
Maximum 34°C. Minimum 10°C.

Optimum pH 6.8 to 7.0. Minimum 4.5 to 5.0.

Facultative anaerobe.

Source: Isolated from leaf-spot of *Primula polyantha*

Habitat: Pathogenic on *Primula* spp.

72. *Pseudomonas viridilivida* (Brown) Holland. (*Bacterium viridilividum* Brown, Jour. Agr. Res., 4, 1915, 475; Holland, Jour. Bact., 5, 1920, 225; *Phytomonas viridilivida* Bergey et al., Manual, 1st ed., 1923, 187) From Latin, *viridis*, green; *lividus*, blue.

Rods: 1.0 to 1.25 by 1.25 to 3.0 microns  
Motile with 1 to 3 polar flagella Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Slow liquefaction

Beef agar colonies: Cream white, round, smooth, translucent, edges entire

Broth: Turbid, becomes lime green

Milk: Alkaline and clears.

Nitrites not produced from nitrates

Indole is produced.

Not lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 601).

Acid from glucose and sucrose (Burkholder).

Grows well in 4.5 per cent salt. Grows in 7 per cent salt (Burkholder).

Maximum temperature 34.5°C. Minimum 15°C

Aerobic.

Source: Isolated from diseased lettuce from Louisiana.

Habitat: Pathogenic on lettuce, *Lactuca sativa*.

73. *Pseudomonas delphinii* (Smith) Stapp (*Bacillus delphini* Smith, Science, 19, 1904, 417; *Bacterium delphinii* Bryan, Jour. Agr. Res., 29, 1924, 261; Stapp, in Forauer, Handbuch der Pflanzenkrankheiten, 2, 5 Aufl., 1928, 106;

*Phytomonas delphinii* Bergey et al., Manual, 3rd ed., 1930, 261.) From Latin, *delphin*, a dolphin; M.L. *Delphinium*, a generic name.

Rods: 0.6 to 0.8 by 1.5 to 2.0 microns. Chains present. Motile with 1 to 6 polar flagella. Capsules. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefied.

Beef agar slants. Growth thin, smooth, shining, transparent, margins entire, crystals. Agar becomes dark brown.

Broth: Turbid in 24 hours with delicate pellicle.

Milk: Becomes alkaline and clears.

Nitrites not produced from nitrates

Indole not produced.

No H<sub>2</sub>S produced.

Lipolytic action negative (Starr and Burkholder, Phytopath., 32, 1942, 601).

Acid from glucose, galactose and fructose; slightly acid from sucrose. No acid from lactose, maltose, glycerol and mannitol.

Starch: Hydrolysis feeble.

Weak growth in broth plus 4 per cent salt.

Optimum pH 6.7 to 7.1. pH range 5.6 to 8.6

Optimum temperature 25°C. Maximum 30°C. Minimum 1°C or less.

Source: Isolated from black spot of delphinium.

Habitat: Pathogenic on delphinium causing a black spot in the leaves.

74. *Pseudomonas berberidis* (Thornberry and Anderson) Stapp. (*Phytomonas berberidis* Thornberry and Anderson, Jour. Agr. Res., 43, 1931, 36; Stapp, Bot. Rev., 1, 1935, 407, *Bacterium berberidis* Burgwitz, Phytopathogenic Bacteria, Leningrad, 1935, 153.) From M.L. *Berberis*, barberry, generic name.

Rods: 0.5 to 1.0 by 1.5 to 2.5 microns, occurring singly or in pairs. Motile with 2 to 4 polar flagella Capsules present.

Gram-negative (Burkholder); not Gram positive as stated in original description.

## Intestine

*Bacillus*, 815*Bacterium*, 690

Green fluorescent pigment produced in culture (Burkholder).

Gelatin: Not liquefied

Glucose agar slants: Growth moderate, filiform at first, later beaded, raised, smooth, white. Butyrous in consistency.

Milk: Becomes alkaline. No other change.

Nitrites not produced from nitrates.

Indole not produced.

No  $H_2S$  produced.

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid from glucose, galactose, and sucrose. Maltose and rhamnose not utilized (Burkholder).

No gas from carbohydrates

Starch not hydrolyzed.

Optimum temperature 18°C. Maximum 30°C. Minimum 7°C.

Aerobic.

Sources: Repeated isolations from leaves and twigs of barberry.

Habitat: Pathogenic on barberry, *Berberis thunbergii* and *B. vulgaris*.

75. *Pseudomonas coronafaciens* (Elliott) Stapp. (*Bacterium coronafaciens* Elliott, Jour. Agr. Res., 19, 1920, 153; *Phytomonas coronafaciens* Bergey et al., Manual, 1st ed., 1923, 180, Stapp, in Sorauer, Handbuch der Pflanzenkrankheiten, 2, 5 Auf., 1928, 20) From *L. corona*, halo; *faciens*, producing, referring to the lesions on oat blades

Probable synonyms Elliott (Bact. Plant Pathogens, 1930, 122) lists as synonyms, *Bacillus avenae* (Russell, Johns Hopkins Univ. Thesis, 1892) and *Bacillus avenae* Manns (Ohio Agr. Exp. Sta. Bul. 210, 1909, 133; *Phytomonas avenae* Bergey et al., Manual, 3rd ed., 1930, 263).

Rods: 0.65 by 2.3 microns, occurring in chains. Motile with polar flagella. Capsules. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Slow liquefaction.

Nutrient agar colonies: White, becoming

irregularly circular, flat with raised margins.

Broth: Slight turbidity in 24 hours. Heavy pellicle formed.

Milk: Alkaline. A soft curd formed followed by clearing. Curd sometimes absent.

Nitrites not produced from nitrates.

Indole not formed.

No  $H_2S$  formed.

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid but no gas from glucose and sucrose. Starch hydrolysis slight.

Slight growth in broth plus 2 per cent salt.

Optimum temperature 24° to 25°C. Maximum 31°C. Minimum 1°C.

Source: Numerous isolations from blighted blades of oats.

Habitat: Causes a halo spot on oats (*Avena sativa*). Artificial inoculations show barley (*Hordeum vulgare*), rye (*Secale cereale*) and wheat (*Triticum aestivum*) to be susceptible.

75a. *Pseudomonas coronafaciens* var. *atropurpurea* (Reddy and Godkin) Stapp. (*Bacterium coronafaciens* var. *atropurpureum* Reddy and Godkin, *Phytopath.*, 13, 1923, 81; Stapp, in Sorauer, Handbuch der Pflanzenkrankheiten, 2, 5 Auf., 1928, 39, *Phytomonas coronafaciens* var. *atropurpurea* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 371.) From *L. ater*, black, dark; *purpureus*, purple, referring to the color of the lesion on brome grass.

Distinctive characters: This variety differs from *Pseudomonas coronafaciens* in that it infects the brome-grass, *Bromus inermis*, where it produces a water soaked spot which is dark purple in color.

Source: Numerous isolations from diseased brome-grass.

Habitat: Pathogenic on *Bromus inermis* and *Agropyron repens*. Has been artificially inoculated on oats, *Avena sativa*.

76. *Pseudomonas lachrymans* (Smith and Bryan) Carsner. (*Bacterium lachrymans* Smith and Bryan, Jour. Agr. Res., 5, 1915, 466; Carsner, Jour. Agr. Res., 15, 1918, 15; *Bacillus lachrymans* Holland, Jour. Bact., 5, 1920, 218; *Phytomonas lachrymans* Bergey et al., Manual, 1st ed., 1923, 184.) From Latin, causing tears, probably referring to the opaque drops formed on the lesion caused by this pathogen.

Synonym: Elliott (Man. Bact. Plant Pathogens, 1930, 147) lists the following as a synonym: *Bacillus burgeri* Potebna, Khartov Prov. Agr. Exp. Sta., 1, 1915, 37.

Description from Smith and Bryan (*loc. cit.*) and Clara (Cornell Agr. Exp. Sta. Mem. 159, 1934, 26).

Rods: 0.8 by 1 to 2 microns. Motile with 1 to 5 polar flagella. Capsules. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefied.

Beef-peptone agar colonies: Circular, smooth, glistening, transparent, whitish, entire margins.

Broth: Turbid in 24 hours. White precipitate with crystals.

Milk: Turns alkaline and clears.

Nitrites not produced from nitrates.

Indole reaction weak.

No  $H_2S$  produced.

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid but not gas from glucose, fructose, mannose, arabinose, xylose, sucrose and mannitol. Alkaline reaction from salts of citric, malic and succinic acid. Maltose, rhamnose, lactose, raffinose, glycerol and salicin not fermented (Clara, *loc. cit.*).

Starch partially digested. Not digested (Clara, *loc. cit.*)

Growth in 3 per cent salt after 12 days. No growth in 4 per cent salt.

Optimum temperature 25° to 27°C. Maximum 35°C. Minimum 1°C.

Aerobic. Facultative anaerobic (Clara, *loc. cit.*).

Source: Isolated from diseased cucumber leaves collected in New York, Wisconsin, Indiana and in Ontario, Canada.

Habitat: Pathogenic on cucumber, *Cucumis sativus*, and related plants.

77. *Pseudomonas maculicola* (McCulloch) Stevens (*Bacterium maculicolum* McCulloch, U. S. Dept. Agr., Bur. Plant Ind. Bul., 225, 1911, 14; Stevens, The Fungi which cause Plant Diseases, 1913, 28, *Phytomonas maculicola* Bergey et al., Manual, 1st ed., 1923, 189; *Bacterium maccullochianum* Burgwitz, *Phytopathogenic Bacteria*, Leningrad, 1935, 77) From L. *maculus*, spot; *-cola*, dweller.

Rods 0.9 by 1.5 to 3 microns. Filaments present. Motile with 1 to 5 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefied.

Beef-peptone agar colonies: Whitish, circular, shining, translucent, edges entire.

Broth: Turbid. No ring or pellicle.

Milk: Becomes alkaline and clears.

Nitrites not produced from nitrates.

Indole production feeble.

No  $H_2S$  formed.

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid from glucose, galactose, xylose, sucrose, glycerol, and mannitol. Alkaline reaction from salts of citric, malic, malonic, and succinic acid. Salicin, maltose, and salts of hippuric and tartaric not utilized (Burkholder).

Slight growth in broth plus 4 per cent salt (Erw. Smith, *Bact. Plant Diseases*, 1920, 306).

Aerobic.

Optimum temperature 24° to 25°C. Maximum 29°C. Minimum 0°C.

Source: Isolated from diseased cauliflower leaves from Virginia.

Habitat: Pathogenic on cauliflower and cabbage.

NOTE: *Bacterium maculicola* var. *japonicum* Takimoto, Bul. Sci. Fak. Terkult.

—, distillery

*Lactobacillus*, 360

—, mash

*Pseudomonas*, 146

—, pressed

*Flavobacterium*, 613*Lactobacillus*, 358

Kjusu Imp. Univ., 4, 1931, 545 has not been seen.

78. *Pseudomonas marginata* (McCulloch) Stapp. (*Bacterium marginatum* McCulloch, Science, 54, 1921, 115; Jour. Agr. Res., 29, 1921, 174; *Phytomonas marginata* Bergey et al., Manual, 1st ed., 1923, 188; Stapp, in Sorauer, Handbuch der Pflanzenkrankheiten, 2, 5 Auf., 1928, 56.) From *L. marginatus*, having a border, probably refers to the definite margin of the colony.

Rods: 0.5 to 0.6 by 0.8 to 1.8 microns. Motile with 1 to 4 bipolar flagella. Capsules. Gram-negative.

Green fluorescent pigment produced in Uchinsky's and Fermi's solutions.

Gelatin: Liquefied.

Agar colonies: White, circular, smooth, translucent, viscid, with definite margins at first thin but later thick and contoured. Surface wrinkled.

Milk: At first slightly acid, then alkaline. Casein digested.

Nitrites not produced from nitrates.

Indole production slight.

Hydrogen sulfide production slight.

Lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 601).

Acid but not gas from glucose, lactose, sucrose and glycerol.

Starch hydrolysis feeble.

Growth in 3.5 per cent salt. No growth in 4 per cent salt. pH range, 4.6 to 9.1.

Optimum temperature 30° to 32°C.

Maximum 40°C. Minimum 8° to 9°C.

Source: Repeatedly isolated from diseased gladiolus.

Habitat: Pathogenic on *Gladiolus* spp. and *Iris* spp.

79. *Pseudomonas medicaginis* Sackett. (Sackett, Science, 31, 1910, 553; also Colorado Agr. Exp. Sta., Bull. 158, 1910, 11; *Bacillus medicaginis* Holland, Jour. Bact., 5, 1920, 219; *Phytomonas medicaginis* Bergey et al., Manual, 1st ed., 1923, 179; *Bacterium medicaginis* Elliott, Bact. Plant Path., 1930, 162.) From *L.*

*medica*, ancient Media; M.L. *Medicago*, a generic name.

Rods: 0.7 by 1.2 microns. Motile with 1 to 4 flagella. Filaments present. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Not liquefied.

Nutrient agar colonies: Growth in 24 hours whitish, glistening.

Broth: Turbid in 24 hours. Pellicle formed. Viscid sediment.

Milk: Becomes alkaline. No change.

Nitrites not produced from nitrates.

Indole not produced.

No H<sub>2</sub>S produced.

Not lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 601).

Starch not hydrolyzed.

No gas from carbohydrates. Acid from sucrose.

Slight growth in broth plus 3.75 per cent salt.

Optimum temperature 28° to 30°. Maximum 37.5°C.

Aerobic.

Source: Isolated from brown lesions on leaves and stems of alfalfa.

Habitat: Pathogenic on alfalfa, *Medicago* sp.

79a. *Pseudomonas phaseolicola* (Burkholder) Dowson. (*Phytomonas medicaginis* var. *phaseolicola* Burkholder, Phytopath., 16, 1926, 915; *Bacterium medicaginis* var. *phaseolicola* Link and Hull, Bot. Gaz., 83, 1927, 413; *Pseudomonas medicaginis* var. *phaseolicola* Stapp and Kotte, Nachrichtenb. f. d. Deutschen Pflanzenschutzdienst, 9, 1929, 35; Dowson, Brit. Mycol. Soc. Trans., 26, 1943, 10.) From *L. phaseolus*, bean; M.L. *Phaseolus*, a generic name; *cola*, dweller.

Synonym: *Bacterium puerariae* Hedges. (Phytopath., 17, 1927, 48 and 20, 1930, 140; *Phytomonas puerariae* Bergey et al., Manual, 3rd ed., 1930, 267.)

Description from Burkholder and Zaleski (Phytopath., 22, 1932, 85).

Rods: 1 by 2 microns, sometimes slightly curved, filaments present. Motile with polar flagellum Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin stab: Slow liquefaction.

Beef extract agar Whitish, circular colonies, 2 mm. in diameter Edges entire.

Broth: Turbid.

Milk: Alkaline.

Nitrites not produced from nitrates.

Indole not formed.

Hydrogen sulfide not formed

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid but no gas from glucose, fructose, mannose, arabinose, xylose, sucrose and glycerol. No acid from rhamnose, lactose, maltose, mannitol and salicin. Alkali from salts of citric and malic acids, but not from acetic, formic, lactic or tartaric acids. Starch and cellulose not hydrolyzed.

Slight growth in broth plus 4 per cent salt.

Optimum temperature 20° to 23°C. Maximum 33°C. Minimum 2 5°C. (Hedges, *loc cit.*).

Optimum pH 6.7 to 7.3. Maximum 8.8 to 9.2. Minimum 5.0 to 5.3. (Kotte, *Phyt. Zeitsch.*, 2, 1930, 453.)

Microaerophilic

Source: Isolated from leaves, pod and stem of beans showing halo blight.

Habitat: Pathogenic on beans (*Phaseolus vulgaris*), the kudzu vine (*Pueraria hirsuta*) and related plants

80. *Pseudomonas pisi* Sackett. (Sackett, Colorado Agr. Exp. Sta., Bull 218, 1916, 19; *Bacterium pisi* Erw. Smith, An Introduction to Bacterial Diseases of Plants, 1920, 474; *Phytomonas pisi* Bergey et al., Manual, 1st ed., 1923, 181.) From *Gr. pisum*, the pea; M.L. *Pisum*, a generic name.

Rods: 0.68 to 2.26 microns. Motile with a polar flagellum. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction.

Agar slants: Moderate growth in 24 hours, filiform, glistening, grayish-white.

Broth: Turbid with a scum in 5 days.

Milk: Alkaline, soft curd, clears

Nitrites not produced from nitrates.

Indole not produced.

No H<sub>2</sub>S produced.

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid but not gas from glucose, galactose and sucrose.

Starch not hydrolyzed.

Optimum temperature 27° to 28°C. Maximum 37.5°C. Minimum 7°C.

Aerobic.

Source: Ten cultures isolated from 5 collections of diseased peas showing water soaked lesions on stems and petioles.

Habitat: Pathogenic on garden peas, *Pisum sativum* and field peas, *P. sativum* var *arvense*.

81. *Pseudomonas syringae* van Hall. (Kennis der Bakter. Pflanzenziekte, Inaug. Diss., Amsterdam, 1902, 191; *Bacterium syringae* Erw. Smith, Bacteria in Relation to Plant Diseases, 1, 1905, 63; *Phytomonas syringae* Bergey et al., Manual, 3rd ed., 1930, 257) From Latin, *syringa*, a nymph that was changed into a reed; M.L. *Syringa*, a generic name

Synonyms: Bryan (Jour. Agr. Res., 36, 1928, 225) lists *Bacterium citripulcale* C. O. Smith, *Phytopath.*, 3, 1913, 69, and *Bacterium citrarefaciens* Lee, Jour. Agr. Res., 2, 1917, 1 (*Pseudomonas citrarefaciens* Stapp, in Sorauer, Handb. d. Pflanzenkrankheiten, 2, 5 Aufl., 1923, 190). Clara (Cornell Agr. Exp. Sta.

*vignae* Bergey et al., Manual, 1st ed., 1923, 188), *Pseudomonas viridifaciens* Tisdale and Williamson, Jour. Agr. Res., 25, 1923, 141 (*Bacterium viridifaciens* Tisdale and Williams, *ibid.*; *Phytomonas*

*viridifaciens* Bergey et al., Manual, 2nd ed., 1925, 208), and *Phytomonas vignae* var. *leguminophila* Burkholder, Cornell Agr. Exp. Sta. Mem. 127, 1930, 51. Wilson (Phytopath., 30, 1940, 27) lists *Phytomonas cerasi* (Griffin) Bergey et al. (*Pseudomonas cerasus* Griffin, Science, 34, 1911, 615; *Bacillus cerasus* Holland, Jour. Bact., 5, 1920, 217; Bergey et al., Manual, 3rd ed., 1930, 262; *Bacterium cerasi* Elliott, Bact. Plant Pathogens, 1930, 109.) This would include, therefore the following synonyms which have been listed for *Phytomonas cerasi*. Clara (Cornell Agr. Exp. Sta. Mem. 159, 1934, 25) lists *Bacterium trifoliorum* Jones et al. (Jour. Agr. Res., 25, 1923, 471; *Phytomonas trifoliorum* Burkholder, Phytopath., 16, 1926, 922; *Pseudomonas trifoliorum* Stapp, in Sorauer, Handb. d. Pflanzenkrankheiten, 2, 5 Aufl., 1928, 177) and *Bacterium holci* Kendrick (Phytopath., 16, 1926, 236; *Pseudomonas holci* Kendrick, *ibid.*; *Phytomonas holci* Bergey et al., Manual, 3rd ed., 1930, 258). Wilson (Hilgardia, 10, 1936, 213) lists *Pseudomonas prunicola* Wormald (Ann. Appl. Biol., 17, 1930, 725), *Pseudomonas cerasi* var. *prunicola* Wilson (Hilgardia, 8, 1933, 83), *Bacterium citriputeale* C. O. Smith (Phytopath., 4, 1913, 69; *Pseudomonas citriputealis* Stapp, in Sorauer, Handb. d. Pflanzenkrankheiten, 2, 5 Aufl., 1928, 190; *Phytomonas citriputealis* Bergey et al., Manual, 3rd ed., 1930, 278) and *Pseudomonas utiformica* Clara, Science, 75, 1932, 111 (*Phytomonas utiformica* Clara, Cornell Agr. Exp. Sta. Mem. 159, 1934, 29; *Bacterium utiformica* Burgwitz, Phytopathogenic Bacteria, Leningrad, 1935, 444). A probable synonym is *Phytomonas spongiosa* (Aderhold and Ruhland) Magrou (*Bacillus spongiosus* Aderhold and Ruhland, Cent. f. Bakt., II Abt., 15, 1905, 376; *Pseudomonas spongiosa* Braun, Die Landwirtschaft, 41, 42, 1927, 2 pp; *Bacterium spongiosum* Elliott, Man. Bact. Plant Pathogens, 1930, 214; Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 414). C. O. Smith

(Phytopath., 33, 1943, 82) lists the following as a synonym: *Pseudomonas hibisci* (Nakata and Takimoto) Stapp (*Bacterium hibisci* Nakata and Takimoto, Ann. Phytopath. Soc. Japan, 1, 5, 1923, 18; Stapp, in Sorauer, Handbuch der Pflanzenkrankheiten, 5 Aufl., 2, 1928, 203; *Phytomonas hibisci* Bergey et al., Manuals 3rd ed., 1930, 264).

Description from Clara (*loc. cit.*).

Rods: 0.75 to 1.5 by 1.5 to 3.0 microns. Motile with 1 or 2 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction.

Beef-extract agar colonies: Circular, grayish-white with bluish tinge. Surface smooth. Edges entire or irregular.

Broth: Turbid in 36 hours. No pellicle.

Milk: Alkaline.

Nitrites not produced from nitrates.

Indole not produced.

No H<sub>2</sub>S produced.

Not lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 601).

Slight growth in broth plus 4 per cent salt.

Acid but not gas from glucose, galactose, mannose, arabinose, xylose, sucrose, mannitol and glycerol. Alkaline reaction from salts of citric, malic, succinic and lactic acid. Rhamnose, maltose, lactose, raffinose, salicin, and acetic, formic and tartaric acid not fermented.

Starch not hydrolyzed.

Facultative anaerobe.

Source: Van Hall originally isolated the pathogen from lilac.

Habitat: Pathogenic on lilac, citrus, cow peas, beans, lemons, cherries and many unrelated plants.

Sta. Orsini reports the following as a variety—*Bacterium syringae* var. *capsici* Orsini. (Intern. Bull. Plant Prot., 33, 1942, 33.) Pathogenic on the pepper plant (*Capsicum*).

McCulloch, Jour. Agr. Res., 18, 1920, 549; *Phytomonas atrofaciens* Bergey et al., Manual, 1st ed., 1923, 185, Stevens, Plant Disease Fungi, New York, 1925, 22) From Latin, *ater*, black, *faciens*, making, referring to the color of the lesion on wheat.

Rods: 0.6 by 1 to 2.7 microns. Long chains formed in culture. Capsules present. Motile with 1 to 4 polar or bipolar flagella. Gram-negative

Green fluorescent pigment produced in culture.

Gelatin: Liquefied.

Beef-peptone-agar colonies Circular, shining, translucent, white

Broth: Growth never heavy, slight rim, and a delicate pellicle

Milk: Becomes alkaline and clears

Nitrites not produced from nitrates

Indole: Slight production

Hydrogen sulfide: Slight production

Acid and no gas from glucose, galactose and sucrose.

Starch is slightly hydrolyzed

Optimum temperature 25° to 28°C

Maximum 36° to 37°C and minimum below 2°C.

Aerobic.

Sources: Isolated from diseased wheat grains collected throughout United States and Canada.

Habitat: Causes a basal glume-rot of wheat.

83. *Pseudomonas cuminii* (Kovacevski) Dowson (*Phytomonas cuminii* Kovacevski, Bull. Soc. Bot. Bulgarie, 7, 1936, 27; Dowson, Trans. Brit. Mycol. Soc., 20, 1943, 10) From Greek *cuminum*, *cumin*; M. L. *Cuminum*, a generic name

Rods: 0.5 to 0.7 by 1 to 3 microns, occurring in chains and filaments. Motile with 1 to 3 polar flagella. Gram-negative

Green fluorescent pigment formed in culture.

Gelatin: Rapidly liquefied

Potato agar colonies: Grayish-white, circular, glistening, smooth, butyrous

Broth: Moderate turbidity. Pseudorogloea.

Milk: Not coagulated. Casein peptonized.

Nitrites not produced from nitrates

Indole not formed.

No H<sub>2</sub>S formed.

Acid but not gas from glucose and sucrose. No acid from lactose or glycerol. Starch not hydrolyzed

Temperature range 5°C to 31°C.

Aerobic.

Source: Isolated from blighted cumin (*Cuminum*)

Habitat: Pathogenic on cumin and dill.

84. *Pseudomonas desaii* (Burkholder) comb. nov. (*B. pyocyaneus saccharum* Desai, Ind. Jour. Agr. Sci., 5, 1935, 391, *Phytomonas desaii* Burkholder, in Bergey et al., Manual, 5th ed., 1939, 174) Named for Desai who first isolated the species.

Rods: 0.6 to 1.2 by 1.2 to 2.2 microns. Motile with a polar flagellum. Gram-negative.

Green fluorescent pigment produced in culture

Gelatin: Liquefaction.

Agar colonies: Grayish-blue. Raised.

Broth: Light clouding. Pellicle.

Milk: Peptonized without coagulation.

Nitrites not produced from nitrates.

Indole not formed.

Glucose, sucrose, lactose and glycerol fermented without gas.

Starch: Hydrolysis present

Optimum temperature 30°C.

Aerobic

Source: Isolated from stinking rot of sugar cane in India and associated with a white non-pathogenic bacterium.

Habitat: Pathogenic on sugar cane, *Saccharum officinarum*.

85. *Pseudomonas erodii* Lewis. (Phytopath., 4, 1914, 231; *Bacterium erodii* Lewis, *ibid*; *Phytomonas erodii* Bergey et al., Manual, 3rd ed., 1939, 255.) From Greek, *erodius*, heron; M. L. *Erodium*, a generic name.

Rods: 0.6 to 0.8 by 1.2 to 1.8 microns.

Motile with 1 to 3 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction.

Agar stroke: Heavy, smooth, cream-colored growth in 24 hours.

Broth: Dense clouding in 24 hours.

Milk: Turns alkaline and clears, litmus reduced.

Nitrites not produced from nitrates.

Indole produced in 14 days.

No  $H_2S$  produced.

Acid but not gas from glucose, sucrose, lactose and glycerol.

Temperature: No growth at 35°C.

Aerobic, obligate.

Source: Isolations from *Erodium texanum* and 4 varieties of *Pelargonium*.

Habitat: Causes a leaf spot of *Erodium texanum* and *Pelargonium* spp.

86. *Pseudomonas* apII Jagger. (Jagger, Jour. Agr. Res., 21, 1921, 186; *Phytomonas* apII Bergey et al., Manual, 1st ed., 1923, 184; *Pseudomonas jaggeri* Stapp, in Sorauer, Handbuch der Pflanzenkrankheiten, 2, 5 Aufl., 1928, 210; *Bacterium jaggeri* Elliott, Bacterial Plant Pathogens, 1930, 142, *Phytomonas jaggeri* Magrou, in Handuroy et al., Dict. d. Bact. Path., Paris, 1937, 371.) From Latin, *apium*, parsley, M.L. *Apium*, a generic name.

Description from Clara (Cornell Agr. Exp. Sta. Mem. 159, 1934, 24).

Rods: 0.75 to 1.5 by 1.5 to 3.0 microns. Motile with a polar flagellum. Gram-negative.

Green fluorescent pigment produced in various media

Gelatin: Liquefaction.

Beef-extract agar colonies. Circular, glistening, smooth, edges entire Grayish-white with bluish tinge

Broth: Turbid in 36 hours. Pellicle formed.

Milk: Becomes alkaline. No curd

Nitrites not produced from nitrates

Indole not formed.

No  $H_2S$  formed.

Acid but not gas from glucose, galactose, fructose, mannose, arabinose, xylose, sucrose, mannitol and glycerol. Alkaline reaction from salts of acetic, citric, malic and succinic acids. Rhamnose, maltose, lactose, raffinose, salicin, and formic, lactic and tartaric acid are not utilized.

Starch not hydrolyzed.

Facultative anaerobe.

Distinctive characters: Pathogenicity appears limited to celery.

Source: Jagger isolated this repeatedly from diseased celery leaves.

Habitat: Pathogenic on celery, *Apium graveolens*.

87. *Pseudomonas matthiolae* (Briosi and Pavarino) Dowson. (*Bacterium matthiolae* Briosi and Pavarino, Atti della Reale Accad. dei Lincei Rend., 21, 1912, 216; *Phytomonas matthiolae*, Bergey et al., Manual, 3rd ed., 1930, 266; Mushin, Proc. Roy. Soc. Victoria, 53, 1941, 201; Dowson, Trans. Brit. Mycol. Soc., 26, 1943, 10.) From M.L. *Matthiola*, a generic name.

Rods: 0.4 to 0.6 by 2 to 4 microns. Gram-positive. Gram-negative (Mushin, loc. cit.).

Green fluorescent pigment produced in culture.

Gelatin: Liquefied.

Beef agar colonies: White, circular colonies, slightly elevated, margins smooth.

Broth: Slightly turbid. Becomes pale green.

Milk: Coagulation with acid reaction.

Nitrites produced from nitrates (Mushin).

Hydrogen sulfide not formed.

Acid from glucose, galactose, fructose, mannose, rhamnose, glycerol, mannitol, acetic acid, citric acid, formic acid, lactic acid, malic acid, and succinic acid. Feeble acid in maltose. No acid, no gas in lactose, sucrose, raffinose, starch, salicin, and tartaric acid (Mushin).

Optimum temperature 20 to 24°C.

Maximum temperature 38.5 C. Minimum below 0°C. (Mushin).

Limits of growth in broth are pH 4.4 to pH 9.5 (Mushin).

Aerobic.

Source: Isolated from vascular and parenchymatic disease of stocks, *Matthiola incana* var. *annua*.

Habitat: Pathogenic on stocks

Note: Burkholder (Phytopath., 28, 1938, 936) and Santarelli (Rev. di Pat. Veg., 29, 1939, 364) consider this species a synonym of *Pseudomonas syringae*. Adam and Pugsley (Jour. Dept. Agric. Victoria, 52, 1934, 306) give a description of a green fluorescent pathogen on stocks which is similar to *Pseudomonas syringae*. Mushin (loc. cit.) considers *Pseudomonas matthiolae* to be a distinct species.

88. *Pseudomonas mors-prunorum* Wormald. (Jour. Pom. and Hort. Sci., 9, 1931, 251; *Phytomonas mors-prunorum* Wormald, Trans. Brit. Mycol. Soc., 17, 1932, 109; *Bacterium mors-prunorum*, *ibid.*) From *L. mors*, death, *prunus*, plums.

Rods: Motile with a polar flagellum. Gram-positive (1931) Gram-negative (1932).

Note: Possibly a green fluorescent organism since it produces a faint yellow color in Uchinsky's solution

Gelatin: Liquefaction.

Agar colonies: White.

Broth plus 5 per cent sucrose: White and cloudy.

Nitrites not produced from nitrates

Acid but not gas from glucose, lactose, sucrose and glycerol

Starch not hydrolyzed

Strict aerobe.

Distinctive characters: Differs from *Pseudomonas prunicola* (*Pseudomonas syringae*) in that it produces a white cloudy growth in broth plus 5 per cent sucrose; a rapid acid production in nutrient agar plus 5 per cent sucrose, and a faint yellow or no color in Uchinsky's solution.

Source: Isolated from cankers on plum trees in England.

Habitat: Pathogenic on *Prunus* spp.

89. *Pseudomonas rimaefaciens* Koning. (Chron. Bot., 4, 1938, 11; Meded. Phytop. Labor. Willie Comm. Scholt., 14, 1938, 21.) From *L. rima*, fissure; *faciens*, producing.

Rods: 0.6 to 2.4 microns in length. Motile with 1 to 3 polar flagella. Gram-negative.

Yellow-green fluorescent water-soluble pigment produced in culture.

Gelatin: Liquefied.

Agar colonies: Round, convex, smooth, somewhat granular with hyaline edge.

Broth: Turbid. Surface growth with a sediment in a few days.

Milk: Alkaline and clears.

Nitrites not produced from nitrates  
Peptone, asparagin, urea, gelatin, nitrates and ammonia salts are sources of nitrogen

Hydrogen sulfide not produced.

Indole production slight.

Growth with the following carbon sources plus NO<sub>2</sub>, glucose, sucrose, glycerol, succinates, malates, citrates and oxalates. Less growth with mannitol, fructose, galactose, lactose, salicylate. Acid is produced from the sugars. No growth with dextrin, inulin, maltose, lactose, rhamnose, sachein, tartrates, acetates, formates.

Starch not hydrolyzed.

Aerobic

Optimum temperature 25°C. Maximum about 37°C. Very slow growth at 14°C. Thermal death point 42° to 45°C.

Source: Strains of the pathogen isolated from poplar cankers in France and in the Netherlands.

Habitat: Pathogenic on *Populus brambatica*, *P. trichocarpa* and *P. candicans*.

This may be *Pseudomonas syringae* since the characters are the same and both organisms can infect *Impatiens* sp. *Pseudomonas syringae* infects poplars (Elliott, Bacterial Plant Pathogens, 1939, 218).

90. *Pseudomonas papulans* Rose. (Rose, *Phytopath.*, 7, 1917, 198; *Phytomonas papulans* Bergey et al., Manual, 3rd ed., 1930, 267; *Bacterium papulans* Elliott, *Bacterial Plant Pathogens*, 1930, 175; *Phytomonas syringae* var. *papulans* Smith, *Jour. Agr. Res.*, 68, 1914, 291.) From *L. papulans*, forming blisters.

Rods: 0.6 by 0.9 to 2.3 microns. Motile with 1 to 5 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefied

Broth: Moderate turbidity in 24 hours.

Milk: Alkaline and at times a soft coagulum.

Nitrites not produced from nitrates.

Indole: May or may not be produced.  
Acid but not gas formed from glucose and sucrose

Optimum temperature 25° to 28°C.

Maximum 37°C

Source: Twenty five cultures isolated from blisters on apples and from rough bark.

Habitat: Pathogenic on apple trees.

91. *Pseudomonas pseudozoogloeae* (Honing) Stapp (*Bacterium pseudozoogloeae* Honing, *Bull. van Het. Del. Proefstation, Medan*, 1, 1914, 7; Stapp, in Sorauer, *Handbuch der Pflanzenkrankheiten*, 2, 5 Auf., 1928, 274; *Phytomonas pseudozoogloeae* Bergey et al., 3rd ed., 1930, 261.) From Gr., *pseudo*, false; *M. L. zoogloeae*, zoogloea.

Rods: 0.7 to 1.5 by 0.9 to 2.5 microns. Chains. Motile with 1 or 2 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction.

Agar colonies: Round, flat, yellow-gray.

Broth: Moderate turbidity with pseudozoogloea in the pellicle

Milk: Coagulation. No clearing.

Nitrites not produced from nitrates

Indole not formed

Hydrogen sulfide produced

Acid but not gas from glucose, lactose, maltose, sucrose and mannitol.

Facultative anaerobe.

Source: Isolated from the black rust of tobacco.

Habitat: Pathogenic on tobacco, *Nicotiana tabacum*.

92. *Pseudomonas tabaci* (Wolf and Foster) Stevens. (*Bacterium tabacum* Wolf and Foster, *Science*, 46, 1917, 362; also *Jour. Agr. Res.*, 12, 1918, 419; *Phytomonas tabaci* Bergey et al., Manual, 1st ed., 1923, 185; Stevens, *Plant Disease Fungi*, New York, 1925, 31.) From *Nicotiana tabacum*, tobacco.

Rods: 1.2 by 3.3 microns. Motile with a polar flagellum. Gram-negative.

Gelatin: Liquefaction.

Potato agar colonies: Grayish-white, circular, raised, wet-shining, smooth.

Milk: Alkaline; clears.

Nitrites not produced from nitrates.

Indole not formed.

Acid from glucose, galactose, fructose, l-arabinose, xylose, sucrose, pectin, mannitol and glycerol (Braun, *Phytopath.*, 27, 1937, 29)

Ammonium sulfate, potassium nitrate, cystine, glutamic acid, glycine, succinimide, oxamide, acetamide, and urea can be used as nitrogen source (Braun).

Starch not hydrolyzed. Aerobic.

Distinctive character: Braun (*loc. cit.*) states that *Pseudomonas tabaci* and *Pseudomonas angulata* are identical in culture.

Source: Isolated from wildfire lesions on tobacco leaves in North Carolina.

Habitat: Pathogenic on tobacco, *Nicotiana tabacum*.

93 *Pseudomonas lapsa* (Ark) Burkholder. (*Phytomonas lapsa* Ark, *Phytopath.*, 30, 1940, 1; Burkholder, *ibid.*, 32, 1942, 601.) From Latin, *lapsus*, falling, referring to a symptom of the disease.

Rods: 0.56 by 1.55 microns. Motile with 1 to 4 polar flagella.

Produces fluorescence in Uchinsky's Fernu's, and Cohn's solutions.

Gelatin: Liquefied (Burkholder).

Acid but no gas is produced from glucose, sucrose, maltose, lactose, glyc-  
erine, arabinose, xylose, galactose, raf-  
finose and mannitol.

Slight growth in broth plus 5 per cent  
salt (Burkholder).

Source: Isolated from stalk rot of field  
corn in California; also from *Diabrotica*  
beetles.

Habitat: Pathogenic on corn and sugar  
cane.

NOTE: Like *Pseudomonas desiana*.

94. *Pseudomonas bowlesiae* (Lewis  
and Watson) Dowson. (*Phytomonas*  
*bowlesii* Lewis and Watson, *Phytopath.*  
17, 1927, 611; *Bacterium bowlesii* Elliott,  
Bacterial Plant Pathogens, 1930, 96,  
Dowson, Trans. Brit. Mycol. Soc., 26,  
1943, 9) From M. L. *Boulesia*, a generic  
name.

Rods: 0.5 to 0.7 by 1.2 to 1.6 microns,  
occurring singly, in pairs or in short  
chains. Motile with bipolar flagella.  
Gram-negative

Green fluorescent pigment produced in  
culture.

Gelatin: Liquefied.

Agar slants: Yellowish, moist, glistening  
and viscid

Broth: Uniform turbidity throughout  
Heavy viscous sediment in old cultures

Milk: Alkaline; coagulation, with a  
slow peptonization.

Nitrites are produced from nitrates.

Indole is produced.

Hydrogen sulfide is produced

Acid from glucose, maltose and xylose.  
No acid from sucrose.

Optimum temperature 27°C. Maxi-  
mum 37°C. Minimum -1°C.

Optimum pH 7.2. pH range 4.5 to 8.6.  
Aerobic.

Source: Isolated from diseased, water  
soaked spots of *bowlesia*.

Habitat: Pathogenic on *Boulesia sep-  
tentrionalis*.

95. *Pseudomonas intybi* (Swingle)  
Stapp (*Phytomonas intybi* Swingle,

*Phytopath.*, 16, 1925, 730; Stapp, in Sor-  
auner, Handbuch der Pflanzenkrank-  
heiten, 2, 5 Auf., 1928, 291; *Bacterium*  
*intybi* Elliott, Bacterial Plant Pathogens,  
1930, 142.) From Latin, *intibus*, endive

Description from Stapp, Cent. f. Bakt.,  
II Abt., 91, 1935, 232.

Rods: 0.4 to 0.5 by 1.4 to 2.8 microns.  
Motile with one to several polar flagella  
Gram-negative.

Green fluorescent pigment formed in  
culture.

Gelatin: Liquefaction.

Agar colonies: White, glistening, trans-  
parent

Broth: Turbid with fragile pellicle,  
and good sediment.

Milk: Coagulated. Casein not pep-  
tonized.

Nitrites are produced from nitrates  
with the formation of gas.

Indole not formed.

Acid but not gas from arabinose, xylose  
and glucose. No acid from sucrose

Optimum temperature 23° to 28°C.  
Maximum 40° to 42°C. Minimum 0°C.

Distinctive character: Differs from  
*Pseudomonas cichorii* in that it liquefies  
gelatin and produces nitrites from ni-  
trates.

Source: Isolated from French endive,  
*Cichorium intybus* by Swingle, from *C.*  
*endiva* and lettuce, *Lactuca sativa* by  
Stapp.

Habitat: Pathogenic on endive and let-  
tuce, causing a rot.

96. *Pseudomonas marginalis* (Brown)  
Stevens (*Bacterium marginale* Brown,  
Jour. Agr. Res., 15, 1918, 386, *Phytomonas*  
*marginalis* Bergey et al., Manual, 1st ed.,  
1923, 182, Stevens, Plant Disease Fungi,  
New York, 1925, 30) From Latin, *margo*  
(*marginis*), edge, margin; M.L. *mar-  
ginalis*, on the margin, a character of the  
disease.

Description from Brown (*loc. cit.*) and  
Clara (Cornell Agr. Exp. Sta. Mem. 159,  
1931, 27).

Rods: Motile with 1 to 3 polar flagella.  
Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction.

Agar colonies: Cream-colored to yellowish.

Broth: Turbid, with pellicle.

Milk: Alkaline. Soft curd at times.

Nitrites are produced from nitrates.

Not produced (Clara, *loc. cit.*)

Indole not produced.

No H<sub>2</sub>S produced.

Acid but not gas from glucose, galactose, fructose, mannose, arabinose, xylose, rhamnose, mannitol and glycerol. Alkali from salts of acetic, citric, malic, formic, lactic, succinic and tartaric acid. Sucrose, maltose, lactose, raffinose and salicin not fermented (Clara, *loc. cit.*).

Starch hydrolysis feeble. None (Clara, *loc. cit.*).

Optimum temperature 25° to 26°C.

Maximum 38°C. Minimum 0°C.

Aerobic

Source: Isolated from marginal lesion on lettuce from Kansas.

Habitat: Pathogenic on lettuce and related plants

97. *Pseudomonas setariae* (Okabe) *comb. nov.* (*Bacterium setariae* Okabe, Jour. Soc. Trop. Agr. Formosa, 6, 1934, 63; *Phytomonas setariae* Burkholder, in Bergey, Manual, 5th ed., 1939, 183.) From *L. seta*, bristle; -arius, like; *M. L. Setaria*, a generic name.

Rods: 0.4 to 0.8 by 1.8 to 4.4 microns. Motile with a polar, seldom bipolar, flagellum. Gram-negative.

Yellowish water-soluble pigment produced in culture.

Gelatin: Slow liquefaction.

Beef-extract agar colonies: Circular, white, opalescent, smooth, glistening.

Broth: Turbid after 18 hours. Pellicle.

Milk: Alkaline; clears.

Nitrites are produced from nitrates.

Indole is produced.

No H<sub>2</sub>S produced.

Acid but not gas from glucose, galac-

tose and glycerol. No acid from lactose, maltose or sucrose.

Starch: Feeble hydrolysis.

Grows in 3 per cent salt.

Optimum temperature 31° to 34°C. Maximum 42°C.

Aerobic.

Source: Isolated from brown stripe of Italian millet.

Habitat: Pathogenic on Italian millet, *Setaria italica*.

98. *Pseudomonas polycolor* Clara. (Clara, *Phytopath.*, 20, 1930, 704; *Phytomonas polycolor* Clara, *ibid.*, *Bacterium polycolor* Burgwitz, *Phytopathogenic Bacteria*, Leningrad, 1935, 148.) From *Gr. poly*, many; *L. color*, color.

NOTE: Delacroix (Comp. rend. Acad. Sci., Paris, 137, 1903, 454) describes *Bacillus acrogenosus* as being a tobacco pathogen. The organism described by Delacroix might be the same as *Pseudomonas polycolor*. Braun and Elrod (Jour. Bact., 43, 1942, 40) are of the opinion that Clara's pathogen is *Pseudomonas aeruginosa*.

Description taken from Clara (Cornell Agr. Exp. Sta. Mem. 159, 1934, 28).

Rods: 0.75 to 1.2 by 1.05 to 3.0 microns. Motile with 1 or 2 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction.

Beef-extract agar colonies: Grayish-white, circular, raised, thin transparent margins.

Broth: Turbid in 36 hours with thin pellicle.

Milk: Alkaline; no curd.

Nitrites not produced from nitrates

Indole not produced.

No H<sub>2</sub>S produced.

Lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid but not gas from glucose, galactose, fructose, mannose, arabinose, xylose, mannitol and glycerol. Alkaline reaction from salts of acetic, citric, malic,

lactic and formic acid. Rhamnose, sucrose, maltose, lactose, raffinose and salicin not fermented.

Starch not hydrolyzed.

Facultative anaerobe.

Good growth in broth plus 7 per cent salt.

Optimum temperature 25° to 30°C

Maximum 37° to 39°C.

Distinctive character. Differs from *Pseudomonas mellea* in type of lesion produced, does not digest starch, nor reduce nitrates and does not form acid from lactose nor sucrose. Pathogenic for laboratory animals (Elrod and Braun, Sci. 94, 1941, 520).

Source: Repeatedly isolated from leaf spot of tobacco in the Philippines.

Habitat: Pathogenic on tobacco

99. *Pseudomonas viridiflava* (Burkholder) Clara (*Phylomonas viridiflava* Burk., Cornell Agr. Exp. Sta. Mem 127, 1930, 63; Clara, Science, 75, 1934, 111; *Bacterium viridiflavum* Burgwitz, Phytopathogenic Bacteria, Leningrad, 1935, 127) From Latin *viridis*, green; *flavus*, yellow.

Description from Clara (Cornell Agr. Exp. Sta. Mem. 139, 1934, 30).

Rods. 0.75 to 1.5 by 1.5 to 3.15 microns. Motile with 1 or 2 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction.

Beef-extract agar colonies: Grayish-white, margins corrugated, edges irregular.

Broth: Turbid in 36 hours.

Milk: Becomes alkaline and clears.

Nitrites not produced from nitrates

Indole not formed.

No H<sub>2</sub>S produced.

Not lipolytic (Starr and Burkholder, Phytopath, 32, 1942, 601).

Acid but not gas from glucose, fructose, mannose, arabinose, xylose, mannitol and glycerol. Alkaline reaction from salts of acetic, citric, malic, lactic and

succinic acids. Sucrose, lactose, maltose, raffinose, salicin, and salts of formic and tartaric acids not fermented.

Starch: No hydrolysis.

Growth in broth plus 5 per cent NaCl

Facultative anaerobe.

Source: Two cultures isolated from spotted beans, one from England and one from Switzerland.

Habitat: Pathogenic on bean, *Phaseolus vulgaris*.

99a *Pseudomonas viridiflava* var *concentrica* (Petersen) comb. nov. (*Phylomonas viridiflava* var. *concentrica* Petersen, Tridsskr. f. Planteavl., 38, 1932, 851, *Bacterium viridiflavum* var. *concentricum* Burgwitz, Phytopathogenic Bacteria, Leningrad, 1935, 127.) From M. L. *concentricus*, concentric, referring to the rings on the colonies

Distinctive characters: Differs from *Pseudomonas viridiflava* in that it does not grow in Uchinsky's solution, and also in the shape of the colonies.

Source: Isolated from the stems and leaves of blighted beans in Denmark.

Habitat. Pathogenic on the bean, *Phaseolus vulgaris*.

100. *Pseudomonas ananas* Serrano (Serrano, Philipp. Jour. Sci., 55, 1934, 355; *Phylomonas ananas* and *Bacterium ananas* Serrano, *ibid.* (not to be confused with *Erwinia ananas* Serrano, *ibid.*, 56, 1923, 271); *Bacterium serranoi* Burgwitz, Bact. Dis. of Plants, Leningrad, 1936.) From Brazilian Indian, *ananas*, pineapple; M L *Ananas*, generic name.

Rods. 0.6 by 1.8 microns. Motile with 1 to 4 polar flagella. Gram-negative.

Green fluorescent pigment produced in certain media.

Gelatin: Liquefied.

Beef-extract glucose agar colonies: White, with undulating edges, smooth to rugose, glistening to dull.

Beef-extract agar. Growth scant.

Broth: Feeble growth.

Milk: Becomes alkaline with curd.  
 Nitrites not produced from nitrates.  
 Indole not formed.  
 No  $H_2S$  formed  
 Acid but not gas from glucose, xylose and mannitol. Feeble with lactose. No acid with sucrose.  
 Starch not hydrolyzed.  
 Optimum temperature 30° to 31°C. Maximum 45°C. Minimum 7° to 10°C.  
 Aerobic.  
 Habitat: Causes a rot of pineapples, *Ananas comosus*.

101. *Pseudomonas ligustri* (d'Oliveira) comb. nov. (*Bacterium ligustri* d'Oliveira, Revista Agron., 24, 1936, 434.) From *L. ligustrum*, privet; M. L. *Ligustrum*, a generic name.

Rods 0.5 to 0.7 by 1.3 to 3 microns. No chains. No capsules. Motile with 2 to 5 polar flagella. Gram-negative.

Green pigment produced on Dox agar, and in broth.

Gelatin. Liquefied

Beef-extract agar colonies: Growth moderate. Milky white, circular, convex.

Broth. Turbid in 24 hours. No pellicle.

Milk Coagulated in 6 days, and later digested. Litmus slightly acid.

Nitrites not produced from nitrates  
 Indole not produced.

Ammonia not produced.

No gas from carbohydrates Acid from glucose, galactose, arabinose and mannose. No acid from sucrose, maltose, lactose, raffinose, mannitol and salicin

Source: From diseased Japanese privet in Lisbon, Portugal.

Habitat: Pathogenic on privet, *Ligustrum japonicum*.

102. *Pseudomonas sesami* Malkoff. (Malkoff, Cent f Bakt., II Abt., 16, 1906, 665; *Bacterium sesami* Nakata, Ann. Phyt. Soc. Japan, 2, 1930, 242; *Phytomonas sesami* Kovachersky, Ann. Univ. de Sofia, Fac. Agron., 8, 1930, 464.) From *Gr. sesamum*, sesame; M. L. *Sesamum*, a generic name.

Synonym: Nakata (*loc. cit.*) lists *Bacterium sesamicola* Takimoto, Jour. Plant Protect. Tokyo, 8, 1927, 433 (*Phytomonas sesamicola* Magrou, in Hauduroy et al., Dict. d. Bact. Path., 1937, 412).

Description from Nakata (*loc. cit.*).

Rods: 0.6 to 0.8 by 1.2 to 3.8 microns. Motile with 2 to 5 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction rapid.

Beef-agar colonies: Circular, flat, striate, smooth, entire margins, white.

Broth: Growth rapid. No pellicle.

Milk: Alkaline. No coagulation.

Nitrites not produced from nitrates.

Indole not produced.

No  $H_2S$  produced.

Acid but not gas from glucose. No acid from lactose, sucrose or glycerol.

Starch not hydrolyzed.

Optimum temperature 30°C. Maximum 35°C. Minimum 0°C.

Facultative anaerobe.

Source: Isolated from brown spots on leaves and stems of sesame.

Habitat: Pathogenic on sesame

103. *Pseudomonas tolaasi* Paine. (Paine, Ann. Appl. Biol., 5, 1919, 210; *Phytomonas tolaasi* Bergey et al., Manual, 3rd ed., 1930, 259; *Bacterium tolaasi* Elliott, Bacterial Plant Pathogens, 1930, 226.) Named for A. G. Tolaas who first reported the species.

Rods: 0.4 to 0.5 by 0.9 to 1.7 microns. Motile with 1 to 5 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction.

Bouillon agar: Streak develops in 24 hours, dirty bluish-white, wet-shining and slightly raised.

Broth: Turbid in 24 hours. Pellicle.

Milk: Becomes alkaline and clears

Nitrites not produced from nitrates.

Indole production slight.

Acid but not gas from glucose. No acid from lactose or sucrose.

Starch hydrolysis feeble.

Optimum temperature 25°C.

Source: Isolated in England from brown-spot of cultivated mushrooms

Habitat: Pathogenic on cultivated mushrooms.

101 *Pseudomonas xanthochlora* (Schuster) Stapp (*Bacterium xanthochlorum* Schuster, Arbeit a d Kaiserl Biolog. Anstalt. f. Land. u. Forstw., 8, 1912, 452; *Phytomonas xanthochlora* Bergey et al., Manual, 1st ed., 1923, 180, Stapp, in Sorauer, Handbuch der Pflanzenkrankheiten, 2, 5 Auf., 1928, 213) From Gr. *xanthus*, yellow, *chlorus*, green

Description from Erw. Smith, Bacteria in Rel. to Plant Dis., 3, 1914, 272

Rods 0.75 to 1.5 by 3.0 microns Motile with 1 to 3 flagella. Gram-negative

Green fluorescent pigment produced in culture

Gelatin: Slow liquefaction

Agar colonies. Circular, slightly raised, yellow-white.

Broth. Strong clouding in 24 hours A white pellicle

Milk: Slow coagulation and clearing

Nitrites are produced from nitrates

Indole is produced after 10 days

Hydrogen sulfide produced slowly

Acid but not gas from glucose and galactose.

Optimum temperature 27°C Maximum 44°C. Minimum 2°C

Source Isolated from rotting potato tubers in Germany.

Habitat. Pathogenic on potato tubers and a number of unrelated plants

105 *Pseudomonas rhizoctonia* (Thomson) comb. nov. (*Aplanobacter rhizoctonia* Thomson, Ohio Agr. Exp. Sta. Bull. 359, 1922, 211; *Bacterium rhizoctonia* Stapp, in Sorauer, Handbuch der Pflanzenkrankheiten, 2, 5 Auf., 1928, 290, *Phytomonas rhizoctonia* Burkholder, Phytopath., 20, 1930, 7.) From Gr. *rhizo*, root; *ctonus*, murder.

Rods 0.5 to 0.85 by 1.1 to 1.9 microns Non motile. Gram negative

Green fluorescent pigment produced in culture.

Gelatin: Liquefaction

Nutrient agar colonies Greenish-yellow, later olive-buff, circular, raised, slightly viscid.

Broth. Turbid, pyrite yellow

Milk. Alkaline; clears

Nitrites are produced from nitrates

Indole reaction very slight

No H<sub>2</sub>S formed

Starch: Potato starch slightly hydrolyzed

Growth in 8 per cent salt.

Optimum temperature 25° to 27°C.

Maximum 38°C Minimum 0°C

Source Isolated from roots of lettuce showing the rosette disease

Habitat: Pathogenic on roots of lettuce

106. *Pseudomonas barkeri* (Berridge) Clara (Bacillus of pear blossom disease, Barker and Grove, Ann. Appl. Biol., 1, 1914, 91; Barker and Grove's organism, Doidge, Ann. Appl. Biol., 4, 1917, 50, *B. barkeri* Berridge, Ann. Appl. Biol., 11, 1924, 73; *Phytomonas barkeri* Bergey et al., Manual, 3rd ed., 1930, 265; *Bacterium barkeri* Elliott, Bacterial Plant Pathogens, 1930, 95; Clara, Science, 75, 1934, 11) Named for B. T. P. Barker who first reported the species

Description from Doidge (*loc. cit.*)

Rods 0.5 to 0.8 by 2 to 4 microns Motile with 1 to 4 polar flagella Gram-negative (Burkholder), not Gram-positive as stated

Green fluorescent pigment produced in culture.

Gelatin Liquefaction

Agar Growth is white, feeble, flat, glistening, smooth edged

Broth Slightly turbid in 24 hours

Milk Slowly cleared

Nitrites not produced from nitrates

Indole not formed unless culture warmed.

Starch slowly digested.

Source Barker made many cultures

from blighted pear blossoms. Doidge received a culture from Barker.

Habitat: Causes a blossom blight of pear.

107. *Pseudomonas gladioli* Severini. (Severini, *Annali d. Bot.*, Rome, 11, 1913, 420; *Bacterium gladioli* Elliott, *Bact. Plant Pathogens*, 1930, 132; *Phytomonas gladioli* Magrou, in Hauduroy et al., *Dict. d. Bact. Path.*, Paris, 1937, 356.) From *L. gladiolus*, a little sword; *M. L. Gladiolus*, a generic name.

Rods 0.6 by 2.3 to 2.8 microns. Motile with one or more polar flagella. Gram-negative.

A pale yellow water-soluble pigment found, later orange.

Gelatin colonies. Cream-colored, wart-like. Rapid liquefaction.

Milk: Coagulated and slowly peptonized.

Nitrites not produced from nitrates.

Indole not formed.

No gas.

Aerobic.

Optimum temperature 25° to 30°C.

Habitat: Causes a corm rot of gladiolus and other tubers.

108. *Pseudomonas mellea* Johnson. (*Bacterium melleum* Johnson, *Jour. Agr. Res.*, 23, 1923, 489; Johnson, *loc. cit.*, 489; *Phytomonas mellea* Bergey et al., *Manual*, 3rd ed., 1930, 251.) From *L. melleus*, of or belonging to honey, the color of the colonies.

Rods: 0.6 by 1.8 microns. Capsules. Motile with 1 to 7 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Liquefied.

Potato - glucose agar: Abundant growth, smooth, glistening, viscid, honey-colored.

Broth: Turbid in 24 hours. Pellicle.

Milk: Alkaline; clears.

Nitrites not produced from nitrates.

Indole not formed.

No H<sub>2</sub>S formed.

Starch hydrolysis feeble.

Growth inhibited by 4 per cent salt.

Optimum temperature, 26° to 28°C.

Maximum 36°C.

Facultative anaerobe.

Distinctive character: Differs from *Pseudomonas pseudozoogloeae* in that it produces on tobacco a brown instead of a black spot with a halo, is orange-yellow in culture, and turns milk alkaline.

Source: Isolated from brown rusty spots on tobacco in Wisconsin.

Habitat: Pathogenic on leaves of tobacco, *Nicotiana tabacum*.

109. *Pseudomonas betlis* (Ragunathan) *comb. nov.* (*Bacterium belle* Ragunathan, *Ann. Roy. Card.*, Peradeniya, Ceylon, 11, 1923, 51; *Aplanobacter belle* Elliott, *Bact. Plant Pathogens*, 1930, 4; *Phytomonas bellis* Magrou, in Hauduroy et al., *Dict. d. Bact. Path.*, Paris, 1937, 337.) From Malayan, *belle*, *betel*, a kind of pepper, *Piper betle*.

Rods: 0.5 by 1.5 to 2.5 microns, occurring singly or in short chains. Non-motile. Gram-negative.

Green pigment formed in nutrient gelatin and in broth.

Gelatin: Liquefaction.

Bovril agar colonies: Honey-yellow, circular at first, later echinulate. Raised, smooth and shiny.

Broth: Surface becomes cloudy in 2 days. Pellicle.

No gas from lactose, maltose or sucrose.

Starch is reduced.

Aerobic.

Source: Five cultures isolated from leaf spots on the betel vine.

Habitat: Pathogenic on the betel vine, *Piper betle*.

110. *Pseudomonas panacis* (Takimoto) Dowson. (*Bacterium panaxi* Nakata and Takimoto, *Bul. Agr. Sta. Chosen*, 5, 1922, 1; *Phytomonas panaxi* Magrou, in Hauduroy et al., *Dict. d. Bact. Path.*, Paris, 1937, 339; Dowson, *Trans. Brit.*

Mycol. Soc., 26, 1943, 10.) From *Gr. panax* (*panicis*), a plant heal-all; M. L. *Panax*, a generic name

Description from Elliott, Bact. Plant Pathogens, 1930, 173.

Rods: 0.5 by 1.3 to 1.5 microns. Chains. Motile with 4 to 6 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Slight liquefaction

Agar colonies: White

Milk: Coagulated.

No gas from sugars.

Habitat: Causes a root rot of ginseng, *Panax quinquefolium*.

111. *Pseudomonas aleuritidis* (McCulloch and Demaree) Stapp (*Bacterium aleuritidis* McCulloch and Demaree, Jour. Agr. Res., 45, 1932, 339, Stapp, Bot. Rev., 1, 1935, 408; *Phytomonas aleuritidis* Magrou, in Hauduroy et al., Diet. d. Bact. Path., Paris, 1937, 323) From *Gr. aleurites*, of wheaten flour, M. L. *Aleurites*, generic name.

Rods: 0.6 to 0.7 by 1.1 to 3 microns. Motile with 1 to 5 polar, rarely bipolar, flagella. Capsules present. Gram-negative.

Green fluorescent pigment produced in certain media.

Gelatin: Not liquefied.

Beef agar slants: Growth is thin, white and viscid.

Broth: A heavy white surface growth in 24 hours. Sediment.

Milk: Becomes alkaline, but no separation.

Nitrites are produced from nitrates

Indole test feebly positive

Hydrogen sulfide test feebly positive

Acid but no gas from glucose, galactose and glycerol. Slow acid production from sucrose, maltose and lactose

Starch hydrolysis feeble.

Optimum temperature 27° to 28°C.

Maximum temperature 37°C.

Optimum pH 6.2 to 6.8 pH range 5.4 to 8.9.

Source: Isolations from naturally infected tung oil trees in Georgia.

Habitat: Pathogenic on the tung oil tree (*Aleurites fordii*), on the bean (*Phaseolus vulgaris*) and the castor bean (*Ricinus communis*).

112. *Pseudomonas glycinea* Coerper. (*Bacterium glycineum* Coerper, Jour. Agric. Research, 18, 1919, 188; Coerper, loc. cit., 188; *Phytomonas glycinea* Burkholder, Phytopath., 10, 1926, 922) From *glycys*, sweet; *ine*, like; M. L. *Glycine*, generic name.

Synonym: *Bacterium sojae* Wolf, Phytopath., 10, 1920, 132 (*Phytomonas sojae* Burkholder, Phytopath., 16, 1926, 922; *Pseudomonas sojae* Stapp, in Sorauer, Handb. d. Pflanzenkrankheiten, 2, 5 Aufl., 1928, 174). See Elliott, Bact. Plant Pathogens, 1930, 134; and Shunk and Wolf, Phytopath., 11, 1921, 18.

Rods: 1.2 to 1.5 by 2.3 to 3 microns. Motile with polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: Not liquefied.

Beef-peptone agar colonies: Appear in 24 hours. Circular, creamy white, smooth, shining and convex. Margins entire. Butyrous in consistency.

Milk: Litmus turns blue and later a separation of the milk occurs. Casein not digested.

Nitrites not produced from nitrates

Indole test feebly positive.

Not lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 601).

Starch not hydrolyzed.

Acid from glucose and sucrose

Optimum temperature 21° to 25°C.

Maximum 35°C. Minimum 2°C

Facultative anaerobe.

Source: A number of cultures isolated from soy beans in Wisconsin.

Habitat: Pathogenic on soybean, *Glycine max* (*Soja max*).

*terium soyaе* var. *japonicum* Takimoto, Jour. Plant Protect. Tokyo, 14, 1927, 556; *Bacterium glycineum* var. *japonicum* Elliott, Bact. Plant Pathogens, 1930, 136; *Phytomonas glycinea* var. *japonica* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 358.) From M. L. *Japonicus*, Japanese

Distinctive characters: Differs slightly from *Pseudomonas glycinea* in size of cell, length of chains, action in milk, and color in media. Okabe (Jour. Soc. Trop. Agr., Formosa, 5, 1933, 162) gives a description of the organism which leads one to believe the differences are not great enough to be varietal.

Source: Isolated from leaf spots on soy bean in Formosa.

Habitat: Pathogenic on soy bean, *Glycine max*.

113. *Pseudomonas savastanoi* (Erw. Smith) Stevens (*Bacterium savastanoi* Erw. Smith, U. S. Dept. Agr. Plant Ind. Bull. 131, 1908, 31; Stevens, The Fungi which Cause Plant Diseases, 1913, 33; *Phytomonas savastanoi* Bergey et al., Manual, 1st ed., 1923, 190.) Named for F. Savastano, the Italian plant pathologist.

NOTE: Smith (*loc. cit.*) lists and discards the following species since they were either mixed cultures or names with no descriptions. *Bacterium oleae* Arcangeli, Istit. Bot. delle R. Univ. di Pisa, Ricerche e Lavori, fasc. 1, 1886, 109; *Bacillus oleae tuberculosis* Savastano, Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis., Mat. e Nat., 5, 1889, 92; *Bacillus prilleuxianus* Trevisan, I generi e le specie delle Batteriacee, Milano, 1889, 19; *Bacillus oleae* De Toni and Trevisan, in Saccardo, Sylloge Fungorum, 8, 1889, 982.

Description from Brown, Jour. Agr. Res., 44, 1932, 711.

Rods 0.4 to 0.8 by 1.2 to 3.3 microns. Motile with 1 to 4 polar flagella. Gram-negative.

Green fluorescent pigment found in culture.

Gelatin: No liquefaction.

Beef agar colonies: White, smooth, flat, glistening, margins erose or entire.

Broth: Turbid on the second day. No pellicle or ring.

Milk: Becomes alkaline.

Nitrites not produced from nitrates.

No H<sub>2</sub>S produced.

Acid but not gas from glucose, galactose and sucrose.

Starch is hydrolyzed.

Optimum temperature 23° to 24°C. Maximum 32°C. Minimum 1°C.

Optimum pH 6.8 to 7.0. Maximum 8.5. Minimum 5.6.

Aerobic.

Source: Smith isolated his cultures from olive galls collected in California.

Habitat: Pathogenic on olive.

113a. *Pseudomonas savastanoi* var. *frazini* (Brown) Dowson. (*Bacterium savastanoi* var. *frazini* Brown, Jour. Agr. Res., 44, 1932, 721; *Phytomonas savastanoi* var. *frazini* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 410; *Pseudomonas frazini* Skorje, Ann. Exp. For. Zagreb, 6, 1938, 66; Dowson, Trans. Brit. Mycol. Soc., 26, 1943, 11.) From M. L. *Frazinus*, a generic name.

Distinctive characters: Differs but slightly from *Pseudomonas savastanoi*, but is pathogenic on ash and not on olive.

Source: Three cultures isolated from cankers on ash.

Habitat: Pathogenic on ash, *Frazinus excelsior* and *F. americana*.

114. *Pseudomonas tonelliana* (Ferraris) comb. nov. (*Bacterium tonellianum* Ferraris, Trattato di Patologia e Terapia Vegetale, 3rd ed., 1, 1926, 104; *Phytomonas tonelliana* Adams and Pugsley, Jour. Dept. Agr. Victoria, 32, 1934, 304.) Named for Tonelli, the Italian botanist.

Synonym: *Pseudomonas savastanoi* var. *neri* C. O. Smith, Phytopath., 18, 1928, 503.

Description from Smith (*loc. cit.*) unless otherwise noted.

Rods: 0.5 to 0.6 by 1.5 to 2.5 microns  
Motile with 1 to 3 polar flagella. Gram-negative (Adams and Pugsley, *loc. cit.*).

Gelatin: No liquefaction.

Potato glucose agar colonies: Flat, circular, shining, margins somewhat undulated.

Broth: Dense clouding with partial pellicle.

Milk: Alkaline. No separation

Nitrites not produced from nitrates (Adams and Pugsley).

Indole produced. Not produced (Adams and Pugsley).

Acid but not gas from glucose and sucrose. No acid from lactose (Adams and Pugsley).

Starch not hydrolyzed (Adams and Pugsley).

Distinctive character: *Pseudomonas satastanoi* is similar in culture but is not pathogenic on oleanders.

Source: Both Ferraris and C. O. Smith isolated the pathogen from galls on oleander.

Habitat: Pathogenic on oleander, *Nerium oleander*.

115. *Pseudomonas calendulae* (Takimoto) Dowson. (*Bacterium calendulae* Takimoto, Ann. Phytopath. Soc. Japan, 6, 1936, 311; *Phytomonas calendulae* Burkholder, in Manual, 5th ed., 1939, 201; Dowson, Trans. Brit. Mycol. Soc., 26, 1943, 9.) From Latin, *calendulae*, throughout the month; M. L. *Calendula*, a generic name.

Rods: 0.5 by 1 to 2 microns Motile with 1 to 3 polar flagella Gram-negative.

Green fluorescent pigment produced in Uchinsky's and in Cohn's solutions

Gelatin: Not liquefied.

Agar colonies: Circular, smooth, flat, dirty white.

Broth: Turbid.

Milk: No coagulation

Nitrites not produced from nitrates

Indole formed in small amount.

No  $H_2S$  produced.

Acid but not gas from glucose and glycerol. No acid from lactose or sucrose.

Starch not hydrolyzed

Optimum temperature 27° to 30°C.

Maximum 37°C. Minimum 0° to 7°C.

Habitat. Pathogenic on marigolds, *Calendula officinalis*.

116 *Pseudomonas cichorii* (Swingle) Stapp. (*Phytomonas cichorii* Swingle, Phytopath., 15, 1925, 730; Stapp, in Sorauer, Handbuch der Pflanzenkrankheiten, 2, 5. Aufl., 1928, 291; *Bacterium cichorii* Elliott, Bact. Plant Pathogens, 1930, 112.) From Gr. *cichoria*, chicory; M. L. *Cichorium*, generic name.

Probable synonyms: *Pseudomonas endiviae* Kotte, Phyt. Ztschr., 1, 1930, 609; *Phytomonas endiviae* (Kotte) Clara, Cornell Agr. Exp. Sta. Mem. 159, 1934, 26; and *Bacterium formosanum* Okabe, Jour. Soc. Trop. Agr., Formosa, 7, 1935, 65

Description from Clara (*loc. cit.*) which is a description of a culture of *Pseudomonas endiviae* from Kotte. Swingle's description is very meager.

Rods 0.75 to 1.5 by 1.5 to 3.75 microns. Motile with 1 or 2 polar flagella. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: No liquefaction.

Beef-extract agar colonies. Circular, grayish-white with bluish tinge, raised with slightly irregular edges.

Broth: Turbid in 36 hours with a smooth viscous pellicle.

Milk: Alkaline

Nitrites not produced from nitrates.

Indole not formed.

No  $H_2S$  formed.

Not lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 601).

Acid but not gas from glucose, galactose, fructose, mannose, arabinose, xylose, mannitol and glycerol. Alkaline production from salts of acetic, citric, lactic, malic, succinic and tartaric acids.

Rhamnose, maltose, sucrose, lactose, raffinose and salicin not utilized.

Starch not hydrolyzed.

Slight growth in broth plus 6 per cent NaCl.

Optimum pH 6.8 to 7.1. Maximum 9.2 to 9.4. Minimum 5.0 to 5.3 (Kotte, Phyt. Ztsch., 2, 1930, 453).

Facultative anaerobe.

Distinctive characters: Differs from *Pseudomonas intybi* in that it does not liquefy gelatin or reduce nitrates to nitrites.

Source: Isolated from rot of French endive, *Cichorium intybus* by Swingle and by Okabe, and from *C. endivia* by Kotte.

Habitat: Pathogenic on endive, lettuce and larkspur.

117. *Pseudomonas cissicola* (Takimoto) comb. nov. (*Aplanobacter cissicola* Takimoto, Ann. Phytopath. Soc. Japan., 9, 1939, 43.) From Greek, *cissus*, ivy; M. L. *Cissus* a generic name.

Rods 0.5 to 0.9 by 1.0 to 2.0 microns. Non-motile. Capsules. Gram-negative.

Green fluorescent pigment formed in Uschinsky's solution.

Gelatin: No liquefaction.

Potato-extract agar colonies: Circular, convex, smooth, and dirty white.

Broth: Feeble clouding followed by precipitation of pellicle and rim.

Nitrites not produced from nitrates.

Indole not formed.

Hydrogen sulfide not produced.

No acid nor gas from sucrose, glucose, lactose and glycerol.

Starch is not digested.

Salt toleration is 3 per cent.

Optimum temperature 30°C. Maximum 35°C. Minimum 10°C. Thermal death point 49° to 50°C.

Source: Isolated from black spots on leaves of Japanese ivy, *Cissus japonica* in Japan.

Habitat. Pathogenic only on *Cissus japonica*

118. *Pseudomonas nectarophila* (Doidge) Rosen and Bleeker. (*Bac-*

*terium nectarophila* Doidge, Ann. Appl. Biol., 4, 1917, 73; *Phylomonas nectarophila* Bergey et al., Manual, 3rd ed., 1930, 262; Rosen and Bleeker, Jour. Agr. Res., 46, 1933, 98.) From Gr. *nectar*, nectar; *philus*, loving.

Rods: 0.5 to 0.7 by 0.6 to 1.5 microns. Motile with 1 to 5 polar flagella. Capsules. Gram-negative.

Green fluorescent pigment produced in culture.

Gelatin: No liquefaction.

Nutrient agar colonies: Yellowish-white, wet-shining, smooth, margins irregular.

Broth: Heavy turbidity in 24 hours. Sediment.

Milk: Cleared.

Nitrites not produced from nitrates. Indole not formed.

Acid from glucose and galactose. No acid from sucrose.

Starch hydrolysis feeble.

Optimum temperature 25 to 30°C.

Facultative anaerobe.

Distinctive character: Differs from *Pseudomonas barkeri* in that it does not liquefy gelatin, nor produce indole. Produces capsules.

Source: Isolated from blighted pear blossoms in South Africa.

Habitat: Pathogenic on pear blossoms.

119. *Pseudomonas viburni* (Thornberry and Anderson) Stapp. (*Phylomonas viburni* Thornberry and Anderson, Phytopath., 21, 1931, 912; Stapp, Bot. Rev., 1, 1935, 407; *Bacterium viburni* Burgwitz, Phytopathogenic Bacteria, Leningrad, 1935, 160.) From *L. viburnum*, the way-faring tree; M. L. *Viburnum*, a generic name.

Rods: 0.5 to 1.0 by 1 to 2.0 microns. Capsules present. Motile with 2 to 4 polar flagella. Gram-negative (Burkholder); not Gram-positive as stated.

Green fluorescent pigment produced in culture (Burkholder).

Gelatin: No liquefaction.

Glucose beef-extract colonies: Dull gray, circular, edges entire.

Broth: Turbid with pellicle.

Milk: Alkaline.

Nitrites not produced from nitrates

Indole not formed.

No  $H_2S$  formed.

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601)

Acid from glucose and galactose, but not sucrose (Burkholder).

Starch: No hydrolysis.

Slight growth in 3.5 per cent salt (Burkholder).

Optimum temperature 25°C. Minimum 12°C. Maximum 35°C.

Aerobic.

Source: Isolated from angular leaf spots and stem lesions on arrow-wood, *Viburnum opulus*, etc

Habitat: Pathogenic on *Viburnum* spp.

120. *Pseudomonas mori* (Boyer and Lambert) Stevens. (*Bacterium mori* Boyer and Lambert, *Compt. rend. Acad. Sci. Paris*, 117, 1893, 342; *Bacterium mori* Boyer and Lambert *emend.* Erw Smith, *Science*, 31, 1910, 792, Stevens, *The Fungi which Cause Plant Diseases*, 1913, 30, *Bacillus mori* Holland, *Jour. Bact.*, 5, 1920, 222; *Phytomonas mori* Bergey et al., *Manual*, 1st ed., 1923, 191.) From *Gr. morum*, mulberry; *M. L. Morus*, a generic name

Synonyms: Elliott (*Bact. Plant Pathogens*, 1930, 166) lists *Bacillus cubonians* Macchiati, *Staz. Sperim. Agr. Ital.*, 25, 1892, 228 (Macchiati described the disease due to *Pseudomonas mori*, but gave an incorrect description of the pathogen); also *Bacterium cubonianum* Ferraris, *Curiano le Plante*, 6, 1928, 180 (Ferraris uses Macchiati's name but the description of *Pseudomonas mori*).

Description from Smith (*loc. cit.*)

Rods: 0.9 to 1.3 by 1.8 to 4.5 microns. Motile with a polar flagellum. Gram-negative

Green fluorescent pigment produced in culture.

Gelatin: Not liquefied

Agar colonies: White, slow growing, smooth, flat, edges entire becoming undulate

Milk: Becomes alkaline and clears.

Nitrites not produced from nitrates.

Indole none or feeble production.

Hydrogen sulfide not produced (Okabe, *Jour. Soc. Trop. Agr.*, 5, 1933, 166).

No growth in broth plus 4 per cent salt (Okabe, *loc. cit.*).

No gas from carbohydrates.

Temperature range 1°C to 35°C.

Source: Smith isolated the pathogen from blighted shoots of mulberry from Georgia. Also received cultures from Arkansas and the Pacific Coast.

Habitat: Pathogenic on mulberry, *Morus*.

121. *Pseudomonas stizolobii* (Wolf) *comb. nov.* (*Aplanobacter stizolobii* Wolf, *Phytopath.*, 10, 1920, 79; *Bacterium stizolobii* McCulloch, *Phytopath.*, 18, 1928, 460; *Phytomonas stizolobii* Bergey et al., *Manual*, 3rd ed., 1930, 280.) From *Gr. stizo*, to prick; *lobium*, a little lobe; *Stizolobium*, a generic name.

Rods: 0.6 to 0.7 by 1.0 to 1.6 microns.

Non-motile (Wolf). Motile with a short polar flagellum (McCulloch). Capsules. Gram-negative.

Gelatin: No liquefaction.

Agar colonies: Circular, smooth, white, raised and opaque. Margins entire to slightly undulate.

Broth: Slightly turbid throughout. No pellicle or ring.

Milk: Alkaline.

Nitrites not produced from nitrates.

Indole not formed.

No acid or gas in peptone broth plus sugars.

Starch not hydrolyzed.

Optimum temperature 25° to 28°C.

Distinctive characters: Differs from *Pseudomonas sojae* (*Pseudomonas glycinea*) in the smaller size of cell, and absence of pellicle and dense clouding of broth. The pathogen does not infect soy bean.

Source: Isolated from the leaf spot of velvet bean.

Habitat: Pathogenic on velvet bean, *Stizolobium deeringianum*.

122. *Pseudomonas viciae* Uyeda. (Uyeda in Takimoto, Jour. Plant Protect., Japan, 2, 1915, 845; *Bacterium viciae* Nakata, see Elliott, Bact. Plant Pathogens, 1930, 259; *Phytomonas viciae* Magrou, in Hauduroy et al., Diet. d. Bact. Path., Paris, 1937, 430.) From *L. vicia*, vetch; M. L. *Vicia*, a generic name.

Rods. 0.5 to 0.8 by 1.2 to 2.0 microns. Motile with 2 to 4 polar flagella. Gram-positive.

Green fluorescent pigment produced in culture.

Gelatin colonies: Pale white, glistening, finally turning brown. No liquefaction.

Milk Coagulates and clears.

Nitrites not produced from nitrates.

No H<sub>2</sub>S produced.

Facultative anaerobe.

Habitat Pathogenic on the broad bean (*Vicia faba*), the turnip (*Brassica rapa*), the carrot (*Daucus carota*) and the sweet potato (*Ipomoea batatas*).

123 *Pseudomonas alliicola* Burkholder. (Burkholder, Phytopath., 32, 1942, 146, *Phytomonas alluicola* Burkholder, *ibid.*) From *L. allium*, onion; -cola, dweller.

Rods 0.7 to 1.4 by 1.05 to 2.8 microns. Motile with 1 to several polar flagella, at times bi-polar. Gram-negative.

Gelatin. Liquefaction.

Beef-extract peptone agar streaks: Moderate in growth, white at first, later dirty in appearance, edges wavy, consistency viscid. Medium deep brown.

Potato-glucose agar frequently becomes greenish.

Broth. Turbid with light pellicle. Brown.

Milk. Cleared and litmus reduced. Neutral.

Nitrites produced from nitrates.

Indole not produced.

Hydrogen sulfide not produced.

Lipolytic action very strong.

Acid but no gas from l-arabinose, d-xylose, rhamnose, glucose, d-galactose, fructose, d-lactose, maltose, sucrose,

glycerol, mannitol and salicin. Alkali from salts of acetic, citric, formic, hippuric, lactic, malic, succinic, tartaric acids.

Starch not hydrolysed.

Slight growth in broth plus 4 per cent salt.

Aerobic.

Optimum temperature 30°C. Maximum 41°C. Minimum 5°C.

Source: Seven isolates from storage rot of onion bulbs.

Habitat: Pathogenic on onion bulbs, *Allium cepa*.

124. *Pseudomonas gardeniae* Burkholder and Pirone. (Burkholder and Pirone, Phytopath., 31, 1941, 194; *Phytomonas gardeniae* Burkholder and Pirone, *ibid.*) From M. L. *Gardenia*, a generic name.

Rods: 0.75 by 2.4 microns. Motile with 1 to 2 polar flagella. Gram-negative.

Gelatin: Liquefaction.

Beef-extract peptone agar colonies: Growth fair, white to dirty gray and viscid. Medium becoming dark brown.

Potato-glucose agar: No brown color.

Broth: Turbid with pellicle. Dark brown.

Milk: Soft curd with pellicle. Clears in zones. Litmus reduced.

Nitrites produced from nitrates.

Hydrogen sulfide not produced.

Indole not formed.

Acid from glucose, galactose, xylose, rhamnose, sucrose, maltose, mannitol, glycerol, and salicin. Alkali produced from the salts of citric, malic, malonic, succinic, tartaric and hyppuric acids. Good growth in tyrosine and in asparagine broth.

Starch is not hydrolyzed.

Aerobic.

Source: Eight isolates from leaf spots of gardenias in New Jersey.

Habitat: Pathogenic on leaves of *Gardenia jasminoides*.

125 *Pseudomonas caryophylli* Burkholder. (Burkholder, Phytopath., 31,

1941, 143; *Phylomonas caryophylli*, Burkholder, *ibid.*) From M. L. *Caryophyllus*, an old generic name.

Rods: 0.35 to 0.95 by 1.05 to 3.18 microns. At times slightly curved. Motile with 1 to several polar flagella. Frequently bipolar. Gram-negative.

Gelatin: Liquefaction after 3 to 4 weeks.

Potato glucose agar colonies 3 to 4 mm in diameter, circular, smooth, glistening, edges entire. Color is tan to gray mauve. Old culture dark brown. Consistency butyrous.

Broth: Turbid with a white sediment

Milk: Litmus slowly becomes blue  
Slight reduction at bottom of tube. No clearing.

Nitrites produced from nitrates Also ammonia and gas are produced in a synthetic nitrate medium. Asparagine,  $KNO_3$  and  $NH_4H_2PO_4$  can be utilized

Indole not formed.

Hydrogen sulfide not formed.

Lipolytic action slight to moderate

Acid from l-arabinose, d-xylose, rhamnose, glucose, d-galactose, fructose, d-lactose, maltose, and sucrose, glycerol, mannitol, and salicin. Alkali with sodium salts of acetic, citric, formic, hippuric, lactic, malic, maleic, succinic and tartaric acid.

Starch not hydrolyzed.

Aerobic.

Optimum temperature 30° to 33°C.

Maximum 46°C. Minimum 5°C. or less

Slight growth in broth plus 3.5 per cent salt.

Source: Isolated first by L. K. Jones and later by W. H. Burkholder from dying carnation plants from Spokane, Washington. Twelve isolates used in description.

Habitat: Pathogenic on roots and stalks of the carnation, *Dianthus caryophyllus*.

126. *Pseudomonas solanacearum* Erw. Smith. (*Bacillus solanacearum* Erw. Smith, U. S. Dept. Agr., Div. Veg. Phys. and Path., Bul. 12, 1896, 10; *Bacterium*

*solanacearum* Chester, Ann. Rept. Del. Col. Agr. Exp. Sta., 9, 1897, 73; Erw. Smith, Bacteria in Relation to Plant Diseases, 3, 1914, 178; *Phytomonas solanacearum* Bergey et al., Manual, 1st ed., 1923, 186.) From *L. solanum* nightshade, M. L. *Solanaceae*, a plant family.

Probable synonyms Elliott (Bact. Plant Pathogens, 1930, 203) lists the following: *Bacillus nicotianae* Uyeda, Cent. f. Bakt., II Abt., 13, 1904, 327; *Bacillus sesami* Malkoff and *Pseudomonas sesami* Malkoff, Cent. f. Bakt., II Abt., 16, 1906, 664; *Bacillus musae* Rorer, Phytopath., 1, 1911, 45; *Bacillus musarum* Zeman, Rev. Facul. Agr. Univ., La Plat., 14, 1921, 17, *Erwinia nicotianae* Bergey et al., Manual, 1st ed., 1923, 172; *Phytomonas ricini* Archibald, Trop. Agr., Trinidad, 4, 1927, 124

Description taken from Elliott (*loc. cit.*).

Rods: 0.5 to 1.5 microns. Motile with a polar flagellum. Gram-negative.

Gelatin: Nakata (Jour. Sci. Agr. Soc. Tokyo, 294, 1927, 216) states there are two forms, one of which shows slight liquefaction. The other shows no liquefaction.

Agar colonies: Small, irregular, roundish, smooth, wet-shining, opalescent, becoming brown.

Broth: Slight pellicle. Broth turns brown.

Milk: Cleared without precipitation of casein.

Nitrites produced from nitrates.

Indole not formed

Hydrogen sulfide not produced (Burkholder)

Glucose, sucrose, glycerol, sodium

1038, 325).

Nitrogen sources utilized are ammonia, nitrates ( $KNO_3$ ) asparagine, tyrosine, peptone and glutamic acid, but not potassium nitrite (Mushin, *loc. cit.*).

Starch not hydrolyzed.

Garden, 9, 1922, 383; *Bacterium albo-precipitans* Elliott, Bact. Plant Path., 1930, 89; *Phytomonas alboprecipitans* Bergey et al., Manual, 3rd ed., 1930, 277.) From Latin *albus*, white and *precipitans*, precipitating, referring to the white precipitate produced in culture.

Rods: 0.6 by 1.8 microns, occurring singly or in pairs. Capsules present. Motile with a polar flagellum. Gram-negative.

Gelatin. Not liquefied.

Nutrient agar colonies. White, circular, raised, smooth, sticky, with margins entire. Whitish discoloration of the medium.

Broth: Turbid in 24 hours. Heavy sediment in old cultures.

Milk: Becomes alkaline and slowly clears

Nitrites produced from nitrates.

Indole not produced

No H<sub>2</sub>S produced.

Acid but not gas from glucose, fructose, glycerol and mannitol. No acid from lactose, maltose or sucrose.

Starch is hydrolyzed

Optimum temperature 30° to 35°C. Maximum temperature 40°C. Minimum 0°C.

Aerobic

Distinctive characteristics. White precipitate in culture media.

Source: Isolated a number of times from foxtail grass.

Habitat. Pathogenic on foxtail, *Chaetochloa lutescens* and other grasses.

141. *Pseudomonas petasitis* (Takimoto) comb. nov. (*Bacterium petasitis* Takimoto, Ann. Phyt. Soc. Japan, 2, 1927, 55; *Phytomonas petasitis* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 393.) From M. L. *Petasites*, a generic name.

Rods. 0.8 to 1.1 by 1.1 to 1.7 microns. Motile with a polar flagellum. Gram-negative.

Gelatin. No liquefaction.

Beef agar colonies: White, circular or ameboid, butyrous.

Broth: Strong turbidity. Pellicle.

Milk: Coagulated in 30 days.

Nitrites produced from nitrates with gas formation.

Indole not produced.

No H<sub>2</sub>S produced.

No evident acid in peptone broth but gas from glucose, lactose and sucrose. Acid but not gas from glycerol.

Weak growth in broth plus 6 percent salt.

Optimum temperature 27° to 30°C. Maximum 47°C. Minimum approximately 5°C.

Source: Isolated from brown to black lesions on *Petasites japonicus* in Japan.

Habitat: Pathogenic on leaves of *Petasites japonicus*.

142. *Pseudomonas lignicola* Westerdijk and Buisman. (De Iepenziekte, Arnhem, 1929, 51.) From Latin, *lignum*, wood; *-cola*, dweller.

Rods: Single or short chains. Motile with 1 to several polar flagella. Gram-negative.

Gelatin: No liquefaction.

Malt agar streaks: Milk white with a colorless edge.

Broth: Turbid with light pellicle.

Milk: No coagulation. No acid.

Nitrites not produced from nitrates.

Indole not formed.

Starch hydrolysis slight.

Optimum temperature ±25°C.

Source: From vessels of elm wood showing dark discoloration, in Holland.

Habitat: Pathogenic in elm wood

143. *Pseudomonas andropogoni* (Erw. Smith) Stapp. (*Bacterium andropogoni* Erw. Smith, Bacteria in Relation to Plant Diseases, 2, 1911, 63; Elliott and Smith, Jour. Agr. Res., 38, 1929, 4; Stapp, in Sorauer, Handbuch der Pflanzenkrankheiten, 2, 5 Auf., 1928, 27; *Phytomonas andropogoni* Bergey et al., Manual, 3rd ed., 1930, 276.) From M.

*L. Andropogon*, a generic name (a synonym of *Holcus*).

Description from Elliott and Smith (*loc. cit.*).

Rods: 0.61 by 1.76 microns Motile with one to several bipolar flagella Capsules. Gram-negative.

Gelatin: Feeble liquefaction or none

Beef-extract agar colonies Slow-growing, round, smooth, glistening, viscid, white.

Broth: Growth slow with moderate turbidity in 48 hours A thin pellicle

Milk: Alkaline and clears

Nitrites not produced from nitrates

Indole not formed.

No  $H_2S$  formed.

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid but not gas from glucose, arabinose, fructose and xylose. No acid from sucrose, maltose, lactose, raffinose, glycerol and mannitol.

Starch partially digested.

Optimum temperature 22° to 30°C

Maximum 37° to 38°C. Minimum 15°C

Optimum pH 6.0 to 6.6. Maximum 8.3 to 8.6. Minimum 5.0.

Source: Elliott used for her description 4 cultures isolated from lesions on sorgo, sorghum and broom-corn

Habitat. Pathogenic on sorghum, *Holcus sorghum*.

144. *Pseudomonas woodsii* (Smith) Stevens. (*Bacterium woodsii* Erw. Smith, *Bact. in Relation to Plant Diseases*, 2, 1911, 62, Stevens, *Plant Disease Fungi*, New York, 1925, 39; *Phytomonas woodsii* Bergey et al., *Manual*, 3rd ed., 1930, 256.) Named for A. F. Woods, American plant pathologist.

Description from Burkholder and Gutterman, *Phytopath.*, 25, 1935, 118.

Rods: 0.67 by 1.56 microns. Motile with a polar flagellum. Gram-negative.

Gelatin: No liquefaction.

Beef-extract agar slants Growth slow and scant, filament, creamy, butyrous.

Broth: Turbid

Milk: Becomes alkaline but otherwise little changed.

Nitrites not produced from nitrates.

Indole not formed.

No  $H_2S$  formed.

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 601).

Acid but not gas from glucose, fructose, galactose, arabinose, xylose, rhamnose, lactose, glycerol and mannitol. Alkaline reaction from salts of acetic, citric, malic and succinic acids. Sucrose, maltose, salicin, and lactic and formic acids not fermented. Starch not hydrolyzed.

Slight growth in broth plus 3 per cent salt.

Aerobic.

Source: Isolated from water-soaked lesions on carnation leaves

Habitat: Pathogenic on carnation, *Dianthus caryophyllus*.

145. *Pseudomonas panici-miliacei* (Ikata and Yamauchi) *comb. nov.* (*Bacterium panici-miliacei* Ikata and Yamauchi, *Jour. Plant Protect.*, 18, 1931, 35; *Phytomonas panici-miliacei* Burkholder, in *Manual*, 5th ed., 1939, 201) from *M. L. Panicum miliaceum*.

Description translated by Dr. K. Tognashi

Rods: 0.8 to 1.1 by 1.8 to 2.6 microns Motile, with a single flagellum. Gram-negative.

Gelatin: Not liquefied.

Potato-agar plates Growth moderate, whitish, then tinged with light orange, undulating margins.

Broth. Turbid, white pellicle formed.

Milk: No coagulation and slow digestion. Alkaline

Nitrites are produced from nitrates

Indole not formed.

No  $H_2S$  produced.

No acid and no gas from sucrose, glucose, lactose, glycerol and sodium nitrate.

Starch not hydrolyzed.

Optimum temperature 30° to 35°C

Facultative anaerobe.

Source. Species first isolated from millet, *Panicum miliaceum*.

Habitat Causes a leaf stripe of *Panicum miliaceum*.

146 *Pseudomonas saliciperda* Lindeijer (Lindeijer, Inaug Diss, Univ. Amsterdam, 1932; *Phytopath. Ztschr.*, 6, 1933, 373, *Bacterium saliciperda* Burgwitz, *Phytopathogenic Bacteria*, Leningrad, 1935, 106; *Phytomonas saliciperda* Magrou, in Hauduroy et al., *Dict. d. Bact. Path.*, Paris, 1937, 408) From *L. salix* (*salicis*), willow; *perdo*, to destroy.

Rods 12 to 21 microns in length. Motile with a polar flagellum. Gram-negative

Gelatin. No liquefaction.

Beef wort agar colonies: Gray-white.

Milk No acid nor coagulation.

Nitrites produced (small amount) from nitrates

Indole formation slight.

No gas from carbohydrates.

Starch not hydrolyzed.

Facultative anaerobe.

Source. Isolated from wilted branches of willow and pathogenicity proved

Habitat Pathogenic on willow, *Salix spp.*

147 *Pseudomonas eriobotryae* (Takimoto) Dowson (*Bacterium eriobotryae* Takimoto, *Jour. Plant Protect.*, 18, 1931, 354, *Phytomonas eriobotryae* Burkholder, in *Manual*, 5th ed, 1939, 205; Dowson, *Trans. Brit. Mycol. Soc.*, 26, 1943, 10.) From M. L. *Eriobotrya*, a generic name.

Translated by Dr. K. Togashi.

Rods 0.7 to 0.9 by 2.2 to 3.0 microns. Motile, with 1 or 2 flagella. Gram-negative.

Gelatin. Not liquefied

Agar plates. Colonies appear after 3 days, white or hyaline, butyrous, margins entire.

Broth Moderately turbid, pellicle powdery, ring formed

Milk: No coagulation, peptonized slowly. Alkaline

Nitrites not produced from nitrates.

Indole not formed.

No H<sub>2</sub>S produced.

No acid or gas from glucose, sucrose, lactose and glycerol in broth.

Starch not hydrolyzed.

Temperature relations: Minimum below 4°C, optimum 25° to 26°C, and maximum 32°C. Thermal death point 51°C.

Aerobic.

Source: Species isolated from loquat, *Eriobotrya japonica*.

Habitat: Causes a bud rot of *Eriobotrya japonica*.

148. *Pseudomonas wieringae* (Elliott) *comb. nov.* (*Phytomonas betae* Wieringa, *Nederl. Tijdschr. Hyg., Microbiol. en Serol.*, Leiden, 2, 1927, 148; *Bacterium wieringae* Elliott, *Man. Bact. Plant Pathogens*, 1930, 264; *Phytomonas wieringae* Burkholder, in *Manual*, 5th ed, 1939, 206) Named for K. L. Wieringa, plant pathologist of Holland.

Because *Bacterium betae* Chester (*Ann. Rept. Del. Col. Agr. Exp. Sta.*, 9, 1897, 53) may be a pseudomonad, the species name proposed by Elliott has been retained.

Description from Elliott (*loc. cit.*).

Rods: 0.5 to 2.0 microns. Motile with 1 to 5 polar flagella. Gram-negative.

Beef-agar colonies: Smooth, round, white to grayish, fluorescent.

Milk: Cleared in 5 days. Not coagulated.

Nitrites not produced from nitrates.

No gas from sugars.

Optimum temperature 28° to 30°C. Maximum 37°C. Minimum 4°C.

Source: Isolated from vascular rot of beets in Holland.

Habitat: Pathogenic on beets, *Beta vulgaris*.

**Appendix I\*:** The following species are believed to belong in the genus *Pseudomonas* although descriptions are frequently incomplete.

*Achromobacter pellucidum* Harrison. (Canadian Jour. Res., 1, 1929, 236.) Isolated from halibut. For a description of this species, see Bergey et al., Manual, 5th ed., 1939, 619.

*Bacillus aurantiacus tingitanus* Remlinger and Bailly. (Maroc Medical, No 150, 1935; See Lasseur, Dupaix and Babou, Trav. Lab. Microbiol. Fac. Pharm. Nancy, Fasc. 8, 1935, 41.) From water. Dissociates readily. Related to *Pseudomonas fluorescens aureus* Zimmermann. See p. 645.

*Bacillus cyaneofluorescens* Zangemeister. (Cent. f. Bakt., I Abt., 18, 1895, 321; *Pseudomonas cyaneofluorescens* Migula, Syst. d. Bakt., 2, 1900, 906.) From blue milk.

*Bacillus fluorescens nivalis* Eisenberg (Eine Gletscherbakterie, Schmelck, Cent. f. Bakt., 4, 1888, 545; Eisenberg, Bakt. Diag., 3 Aufl., 1891, 77.) From the melting snow of a glacier. Probably a synonym of *Pseudomonas fluorescens*.

*Bacillus lactis saponacei* Weigmann and Zirn. (Cent. f. Bakt., 16, 1891, 468.) From soapy milk.

*Bacterium auxinophilum* Jacobs. (Ann. Appl. Biol., 22, 1935, 619.) A Gram-negative organism with a polar flagellum which liquefies gelatin rapidly.

*Bacterium bosporum* Kalnigš. (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 259.) Decomposes cellulose. Single polar flagellum. From soil.

*Bacterium briosii* Pavarino (Atti Ist. Bot. d. R. Univ. di Pavia, Ser. 2, 12, 1910, 337.) The natural host is *Lycopersicon esculentum*. Pavarino (Rev. di Patol. Veg., 6, 1913, 161) states that this organism and *Phytobacter lycopersicum* Groeneweg (Meded. Rijks Hoogere Land, Tuin- en Boschbouwschool, Dell 5, 5, 1912, 217) should be considered identi-

cal. It closely resembles *Bacterium vesicatorium* Doidge (Jour. Dept. Agr. So. Africa, 1, 1920, 718) according to Gardner and Kendrick (Jour. Agr. Res., 21, 1921, 140).

*Bacterium elaphorum* Kalnigš. (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 257.) Decomposes cellulose. Single polar flagellum. From soil.

*Bacterium fraenkelii* Hashimoto. (Zeit. f. Hyg., 51, 1899, 88.) A pleomorphic polar flagellate bacterium. From milk.

*Bacterium gummi* Comes. (Comes, Napoli, Maggio 18, 1884, 14; see Comes, Atti d. R. Ist. d'incoraggiamento alli Sc., Ser. 3, 3, 1884, 4; *Bacillus gummi* Trevisan, I generi e le specie delle Batteriacee, Milano, 1889, 17.) Pathogenic on grapes, *Vitis* spp.

*Bacterium krameriani* Pavarino. (Atti R. Accad. Naz. Lincei Rend. Cl. Sci. Fis., Mat. et Nat., 20, 1911, 233.) Pathogenic on the orchid, *Oncidium krameriani*.

*Bacterium pusiolum* Kalnigš. (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 261.) Decomposes cellulose. Single polar flagellum. From manure.

*Bacterium protozoides* Kalnigš. (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 263.) Decomposes cellulose. Single polar flagellum. From soil.

*Pseudomonas acuta* Migula (Culture No. 11, Lembke, Arch. f. Hyg., 29, 1897, 317; Migula, Syst. d. Bakt., 2, 1900, 921.) From the intestine.

*Pseudomonas alba* Migula. (*Bacillus fluorescens albus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, I Reihe, 1890, 18, Migula, Syst. d. Bakt., 2, 1900, 909.) From water. *Bacillus fluorescens non liquefaciens* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 145 may be identical according to Migula (*loc. cit.*).

*Pseudomonas allii* (Griffiths) Migula. (*Bacterium allium* Griffiths, Proc. Roy. Soc. Edinburgh, 51, 1887, 40; Migula,

\* Appendixes I and II prepared by Prof. Robert S. Breed, New York State Experiment Station, Geneva, New York, July, 1913.

Syst. d. Bakt., 2, 1900, 932) From rotted onions.

*Pseudomonas aquatilis* Migula. (Tataroff, Inaug. Diss., Dorpat, 1891, 31; Migula, Syst. d. Bakt., 2, 1900, 933.) From water. Said to form spores.

*Pseudomonas aromatica* Migula. (*Bacillus crassus aromaticus* Tataroff, Inaug. Diss., Dorpat, 1891, 27; Migula, Syst. d. Bakt., 2, 1900, 880.) From water.

*Pseudomonas aromatica* var. *quercito-pyrogallica* Kluyver, Hof and Boezaardt. (Enzymologia, 7 1939, 28.)

*Pseudomonas articulata* Kern. (Arb. bakt. Inst. Karlsruhe, 1, Heft 4, 1896, 462.) From the stomachs of birds.

*Pseudomonas aucubicola* Trapp. (Phytopath., 26, 1936, 264.) Isolated from *Aucuba japonica* Not pathogenic.

*Pseudomonas aurea* Migula (*Bacillus fluorescens aureus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, I Reihe, 1890, 14; Migula, Syst. d. Bakt., 2, 1900, 931.) From water.

*Pseudomonas brassicae acidiae* Gruber (Cent. f. Bakt., II Abt., 22, 1909, 558). From sauerkraut. Identical with *Bacterium brassicae acidiae* Conrad (Arch. f. Hyg., 29, 1897, 75) according to Lehmann and Neumann (Bakt. Diag., 5 Aufl., 2 1912, 380.)

*Pseudomonas butyri* Migula. (*Bacillus butyri fluorescens* Lafar, Arch. f. Hyg., 13, 1891, 19; Migula, Syst. d. Bakt., 2, 1900, 894.) From butter.

*Pseudomonas calciphila* Mohs. (Cent. f. Bakt., II Abt., 65, 1925, 136.) From fresh water. Deposits  $\text{CaCO}_3$ .

*Pseudomonas calco-acetica* Clifton. (Enzymologia, 4, 1937, 246.)

*Pseudomonas capsulata* Migula. (Syst. d. Bakt., 2, 1900, 915; not *Pseudomonas capsulata* Bergey et al., Manual, 1st ed., 1923, 124.) Similar to *Pseudomonas macroselmis* Migula.

*Pseudomonas caryocyanea* (Dupaix) Beijerinck. (*Bacillus caryocyanus* Dupaix, Thesis, Univ. of Nancy, 1933, 1; Beijerinck, see Dupaix, *ibid.*, 13; *Bac-*

*terium caryocyanum* Dupaix, *ibid.*, 246.) Isolated from rotten willow wood, from yeast mash and beer-wort. Name appears first as *Bacillus caryocyanus* on a culture sent by Beijerinck from Delft, Holland to the National Collection of Type Cultures, Lister Institute, London. Regarded by Dupaix as closely related to *Bacillus cyano-fluorescens* Zangemeister (Cent. f. Bakt., I Abt., 18, 1895, 321; *Pseudomonas cyano-fluorescens* Migula, Syst. d. Bakt., 2, 1900, 906); Der blaue *Bacillus*, Mildenberg (Cent. f. Bakt., II Abt., 56, 1922, 309; *Pseudomonas mildenbergii* Bergey et al., Manual, 3rd ed., 1930, 172); and *Bacillus pyocyanus* Gessard (Compt. rend. Acad. Sci. Paris, 94, 1882, 536).

*Pseudomonas catarrhalis* Chester. (*Bacillus* der Hundestaupe, Jess, Cent. f. Bakt., II Abt., 25, 1899, 541; Chester, Man. Determ. Bakt., 1901, 308.) Isolated from catarrh in dogs.

*Pseudomonas caviae* Scherago. (Jour. Bakt., 31, 1936, 83; Jour. Inf. Dis., 60, 1937, 215.) Cause of an epizootic septicemia in guinea pigs.

*Pseudomonas chlorophaena* Migula. (Syst. d. Bakt., 2, 1900, 899.)

*Pseudomonas coccacea* Migula. (Culture No. 10, Lembke, Arch. f. Hyg., 29, 1897, 317; Migula, Syst. d. Bakt., 2, 1900, 924.) From the intestine.

*Pseudomonas cohaerens* (sic) (Wright) Chester. (*Bacillus cohaerens* Wright, Mem. Nat. Acad. Sci., 7, 1895, 464; Chester, Man. Determ. Bakt., 1901, 312.) From water.

*Pseudomonas coli* Migula. (Culture No. 8, Lembke, Arch. f. Hyg., 29, 1897, 315; Migula, Syst. d. Bakt., 2, 1900, 920.) From the intestine.

*Pseudomonas colloides* Migula. (*Bacillus fluorescens putidus colloides* Tataroff, Inaug. Diss., Dorpat, 1891, 40; Migula, Syst. d. Bakt., 2, 1900, 902.) From water. Said to form spores.

*Pseudomonas conradi* Lehmann and Neumann. (Bakt. Diag., 5 Aufl., 2, 1912, 394.) Red pigment.

*Pseudomonas delabens* (Wright) Chester. (*Bacillus delabens* Wright, Mem. Nat. Acad. Sci., 7, 1895, 456, Chester, Man. Determ. Bact., 1901, 314.) From water.

*Pseudomonas duplex* Migula (Culture No. 7, Lembke, Arch. f. Hyg., 29, 1897, 314; Migula, Syst. d. Bakt., 2, 1900, 922.) From the intestine.

*Pseudomonas ellipsoidea* Migula. (*Bacillus oogenes fluorescens*  $\beta$ , Zörkendörfer, Arch. f. Hyg., 16, 1893, 393; Migula, Syst. d. Bakt., 2, 1900, 925.) From hens' eggs.

*Pseudomonas ephemerocyanea* Fuller and Norman. (Jour. Bact., 46, 1913, 274.) From soil. Decomposes cellulose.

*Pseudomonas erythra* Fuller and Norman. (Jour. Bact., 46, 1913, 276.) From soil. Decomposes cellulose.

*Pseudomonas erythrospora* (Cohn) Migula. (*Bacillus erythrosporus* Cohn, Beitr. z. Biol. d. Pflanzen, 3, Heft 1, 1879, 128; Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 29.) From air, meat infusion and water. Said to form spores.

*Pseudomonas fimbriata* (Wright) Chester. (*Bacillus fimbriatus* Wright, Mem. Nat. Acad. Sci., 7, 1895, 463, Chester, Man. Determ. Bact., 1901, 313.) From water.

*Pseudomonas fluorescens exilis* van Hall. (Ztschr. f. Pflanzenkr., 13, 1903, 132.) Causes soft rot of shoots and bulbs of iris (*Iris* spp.).

*Pseudomonas foliacea* Chester (*Bacillus fluorescens foliaceus* Wright, Mem. Nat. Acad. Sci., 7, 1895, 439, Chester, Man. Determ. Bact., 1901, 321, *Bacillus fluorescens-foliaceus* Chester, ibid.) From water. Very similar to *Pseudomonas incognita* Chester.

*Pseudomonas gasiformans* Migula (Ein neuer gasbildender *Bacillus*, Gärtner, Cent. f. Bakt., 15, 1894, 1; Migula, Syst. d. Bakt., 2, 1900, 883.) Gas bubbles in gelatin stab

*Pseudomonas gracilis* Migula. (Syst. d. Bakt., 2, 1900, 888.) Morphologically like *Pseudomonas fluorescens* Migula.

*Pseudomonas granulata* Kern. (Arb. bakt. Inst. Karlsruhe, 1, Heft 4, 1896, 464.) From the stomach and intestine of birds.

*Pseudomonas halestorgus* Elazar-Volcani. (Ph.D. Thesis, Hebrew Univ., Jerusalem, 1910.) A halophilic pseudomonad from the Dead Sea.

*Pseudomonas hydrosulfurea* Migula. (*Bacillus oogenes hydrosulfureus*  $\beta$ , Zörkendörfer, Arch. f. Hyg., 16, 1893, 385; Migula, Syst. d. Bakt., 2, 1900, 898.) From hens' eggs

*Pseudomonas iridis* van Hall. (Van Hall, Thesis, Univ. Amsterdam, 1902 and Ztschr. f. Pflanzenkr., 13, 1903, 129; *Bacterium iridis* Elliott, Man. Bact. Plant Path., 1930, 142, *Phytomonas iridis* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 369.) Causes a rot of bulbs and leaves of iris (*Iris* spp.).

*Pseudomonas iris* (Frick) Migula. (*Bacillus iris* Frick, Arch. f. path. Anat., 116, 1889, 292; according to Eisenberg, Bakt. Diag., 3 Aufl., 1891, 148; Migula, Syst. d. Bakt., 2, 1900, 931.)

*Pseudomonas italica* (Fol and Chiappella) Reinelt (Quoted from Lehmann and Neumann, Bakt. Diag., 7 Aufl., 2, 1927, 367.) Phosphorescent.

*Pseudomonas jaranica* (Eijkmann) Migula (*Photobacterium jaranense* Eijkmann, Genesck Tijdschr. v. Nederl.-Indië, 35, 1892, 109; Abst. in Cent. f. Bakt., 12, 1892, 656, *Bacillus jaranensis* Dyar, Annals New York Acad. Sci., 8, 1895, 359, *Bacterium jaranensis* Chester, Man. Determ. Bact., 1901, 170, *Photobacterium jaranicum* Lehmann and Neumann, Bakt. Diag., 1 Aufl., 2, 1896, 199, Migula, Syst. d. Bakt., 2, 1900, 953.) From sea fish in Java. Blue green luminescence.

*Pseudomonas lactica* Weiss (Arb. bakt. Inst. Karlsruhe, 2, Heft 3, 1902, 238.) From a vegetable infusion

*Pseudomonas lasia* Fuller and Norman

(Jour. Bact., 46, 1943, 275.) From soil. Decomposes cellulose.

*Pseudomonas lembkei* Migula. (Culture No. 12, Lembke, Arch. f. Hyg., 29, 1897, 318; Migula, Syst. d. Bakt., 2, 1900, 896.) From the intestine.

*Pseudomonas liquefaciens* (Tataroff) Migula. (*Bacillus liquefaciens* Tataroff, Inaug. Diss., Dorpat, 1891, 29; Migula, Syst. d. Bakt., 2, 1900, 876.) From water.

*Pseudomonas listeri* Weiss. (Arb. bakt. Inst. Karlsruhe, 2, Heft 3, 1902, 260.) From a vegetable infusion.

*Pseudomonas longa* Migula. (*Bacillus fluorescens longus* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, I Reihe, 1890, 20; Migula, Syst. d. Bakt., 2, 1900, 907) From water.

*Pseudomonas macroselmis* Migula. (*Bacillus fluorescens putidus* Tataroff, Inaug. Diss., Dorpat, 1891, 42; Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 29.) From water.

*Pseudomonas maidis* (Eisenberg) Migula. (*Bacillus maidis* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 119; Migula, Syst. d. Bakt., 2, 1900, 877.) From corn grains soaked in water and from feces of pellagra patients.

*Pseudomonas maschekii* Migula. (Blaugrüner *Bacillus*, Maschek, Bakt. Untersuch. d. Leitmeritzer Trinkwasser, Jahresber. d. Oberrealschule zu Leitmeritz, 1887, Migula, Syst. d. Bakt., 2, 1900, 916.) From water.

*Pseudomonas melochlora* (Winkler and Schrötter) Migula (*Bacillus melochloros* Winkler and Schrötter, Ein neuer grünen Farbstoff entwickelnder Bacillus, Wien, 1890; Migula, Syst. d. Bakt., 2, 1900, 893) From caterpillar feces

*Pseudomonas mesenterica* Migula. (*Bacillus fluorescens mesentericus* Tataroff, Inaug. Diss., Dorpat, 1891, 38; Migula, Syst. d. Bakt., 2, 1900, 903.) From water

*Pseudomonas metalloides* Migula. (*Bacillus rosaceus metalloides* Tataroff, Inaug. Diss., Dorpat, 1891, 65; not *Bacterium rosaceus metalloides* Dowdswell, Ann. de Microgr., 1, 1888-89, 310, see

Heffernan, Cent. f. Bakt., II Abt., 8, 1902, 689; *Pseudomonas rosacea* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 29; Migula, Syst. d. Bakt., 2, 1900, 938.) Single flagellum. Red and yellow-red pigment. From water.

*Pseudomonas minutissima* Migula. (*Bacillus fluorescens liquefaciens minutissimus* Unna and Tommasoli, Monatsh. f. prakt. Dermat., 8, 1889, 57; according to Eisenberg, Bakt. Diag., 3 Aufl., 1891, 76; Migula, Syst. d. Bakt., 2, 1900, 891.) Found on human skin in cases of seborrhoic eczema.

*Pseudomonas mobilis* Migula. (Culture No. 9, Lembke, Arch. f. Hyg., 29, 1897, 316; Migula, Syst. d. Bakt., 2, 1900, 923.) From the intestine.

*Pseudomonas monadiformis* (Kruse) Chester. (*Bacillus coli mobilis* Messica, Riv. d'Igiene, Rome, 1890; *Bacillus monadiformis* Kruse, in Flügge, Die Mikroorganismen, 2, 1896, 374; Chester, Man. Determ. Bact., 1901, 308.) From typhoid stools.

*Pseudomonas mucidolens* Levine and Anderson. (Jour. Bact., 25, 1932, 337.) Causes musty odors in eggs. Also milk (Olsen and Hammer, Iowa State Coll. Jour. Sci., 9, 1934, 125).

*Pseudomonas mucidolens* var. *tarda* Levine and Anderson. (Jour. Bact., 25, 1932, 337.) Causes musty odors in eggs.

*Pseudomonas nexibilis* (Wright) Chester. (*Bacillus nexibilis* Wright, Mem. Nat. Acad. Sci., 7, 1895, 441; Chester, Man. Determ. Bact., 1901, 309.) From water.

*Pseudomonas nivalis* Szilvinyi. (Cent. f. Bakt., II Abt., 94, 1936, 216.) A red chromogen isolated from red snow in Austria.

*Pseudomonas ochroleuca* Migula. (*Bacillus γ*, Zörkendörfer, Arch. f. Hyg., 16, 1893, 396; Migula, Syst. d. Bakt., 2, 1900, 897.) From hens' eggs.

*Pseudomonas oogenes* Migula. (*Bacillus oogenes hydrosulfureus* δ, Zörkendörfer, Arch. f. Hyg., 16, 1893, 386;

Migula, Syst. d. Bakt., 2, 1900, 878.) Single flagellum. From hens' eggs.

*Pseudomonas ovi* Migula. (*Bacillus oogenes* f. Hyg., Bakt., 2)

*Pseudomonas ovicola* Migula. (*Bacillus oogenes fluorescens* γ, Zörkendörfer, Arch. f. Hyg., 16, 1893, 394; Migula, Syst. d. Bakt., 2, 1900, 925.) From hens' eggs.

*Pseudomonas pallescens* Migula. (*Bacillus viridis pallescens* Frick, in Virchow, Arch. f. path. Anat., 116, 1889, 292; according to Eisenberg, Bakt. Diag., 3 Aufl., 1891, 154; Migula, Syst. d. Bakt., 2, 1900, 927.) Source not given

*Pseudomonas pansini* Migula. (*Bacillus fluorescens non liquefaciens* Pansini, in Virchow, Arch. f. path. Anat., 122, 1890, 452; Migula, Syst. d. Bakt., 2, 1900, 926.)

*Pseudomonas pelliculosa* Migula. (*Bacillus oogenes fluorescens* δ, Zörkendörfer, Arch. f. Hyg., 16, 1893, 395; Migula, Syst. d. Bakt., 2, 1900, 926.) From hens' eggs.

*Pseudomonas pellucida* Kern (Arb. bakt. Inst. Karlsruhe, 1, Heft 4, 1896, 465.) From the intestine of birds

*Pseudomonas plehniae* Spieckermann and Thienemann. (Arch. f. Hyg., 74, 1911, 110.) Isolated from carp. Pathogenic for many species of fish.

*Pseudomonas plicata* (Frankland and Frankland) Migula. (*Bacillus plicatus* Frankland and Frankland, Phil. Trans. Roy Soc. London, 178, B, 1887, 273; Migula, Syst. d. Bakt., 2, 1900, 881.) From air.

*Pseudomonas pseudotypbosa* Migula. (Typhusähnlicher *Bacillus*, Lustig, Diag. d. Bakt. d. Wassers, 1893, 16; Migula, Syst. d. Bakt., 2, 1900, 893.) From water.

*Pseudomonas pullulans* (Wright) Chester. (*Bacillus pullulans* Wright, Mem. Nat. Acad. Sci., 7, 1891, 415; Chester, Man. Determ. Bact., 1901, 315.) From water.

*Pseudomonas protea* Frost. (U. S. Public Health Ser., Hyg. Lab. Bull. 66, 1910, 27.) From filtered river water. Can be agglutinated by specific typhoid immune-serum.

*Pseudomonas rosea* Chester. (*Bacillus roseus vini* Bordas, Joulin and Rackowski, Compt. rend. Acad. Sci. Paris, 126, 1898, 1550; Chester, Man. Determ. Bact., 1901, 327; not *Pseudomonas rosea* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 30.) From wine. Said to form spores.

*Pseudomonas (Hydrogenomonas) saccharophila* Doudoroff. (Enzymologia, 9, 1940, 50.) From stagnant water.

*Pseudomonas sapolactica* (Eichholz) De Rossi. (*Bacterium sapolacticum* Eichholz, Cent. f. Bakt., II Abt., 9, 1902, 631, De Rossi, Microbiologia Agraria e Technica, Torino, 1927, 693.) Isolated from soapy milk.

*Pseudomonas sericca* Migula. (Seiden-glänzender *Bacillus*, Tataroff, Inaug. Diss., Dorpat, 1891, 26; Migula, Syst. d. Bakt., 2, 1900, 882.)

*Pseudomonas tenuis* Migula. (*Bacillus fluorescens tenuis* Zimmermann, Bakt. unserer Trink- u. Nutzwässer, I Reihe, 1890, 16, Migula, Syst. d. Bakt., 2, 1900, 910.) From water.

*Pseudomonas trommelschlägel* (Ravenel) Chester. (*Bacillus trommelschlägel* Ravenel, Mem. Nat. Acad. Sci., 8, 1896, 26; Chester, Man. Determ. Bact., 1901, 327.) From soil. Said to form spores.

*Pseudomonas undulata* Chester. (*Bacillus fluorescens undulatus* Ravenel, Mem. Nat. Acad. Sci., 8, 1896, 20; Chester, Man. Determ. Bact., 1901, 328.) From soil. Said to form spores.

*Pseudomonas virescens* (Frick) Migula. (*Bacillus virescens* Frick, Arch. f. path. Anat., 116, 1889, 292; Migula, Syst. d. Bakt., 2, 1900, 916.) From green sputum.

*Pseudomonas viridans* (Symmers) Migula. (*Bacillus viridans* Symmers, Brit. Med. Jour., No. 1615, 1891, 1252; Abst. in Cent. f. Bakt., 12, 1892, 165; Migula, Syst. d. Bakt., 2, 1900, 890.) From water.

*Pseudomonas viridescens* Chester. (Bacillus viridescens liquefaciens Ravenel, Mem Nat. Acad. Sci., 8, 1896, 24; Chester, Man. Determ. Bact., 1901, 328.) From soil. Said to form spores.

*Pseudomonas viridis* Migula. (Bacillus der grünen Diarrhoe der Kinder, Lesage, Arch. d. Physiol. norm. et path., 20, 1888, 212, see Eisenberg, Bakt. Diag., 3 Aufl., 1891, 238, Migula, Syst. d. Bakt., 2, 1900, 886.) From intestine of children.

*Pseudomonas weigmanni* Migula. (Bakterie IV, Weigmann and Zirn, Cent. f. Bakt., 15, 1894, 466; Migula, Syst. d. Bakt., 2, 1900, 892.) From soapy milk.

*Pseudomonas zörkendörferi* Migula. (Bacillus oogenes fluorescens  $\alpha$ , Zörkendorfer, Arch. f. Hyg., 16, 1893, 392; Migula, Syst. d. Bakt., 2, 1900, 897.) From hens' eggs.

**Appendix II:** The following polar flagellate organism has been described from activated sludge. H. Winogradsky has also described polar flagellate forms from the same source that form zoogloea (Compt. rend. Acad. Sci. Paris, 200,

1935, 1887; Ann. Inst. Pasteur, 53, 1937, 333).

*Zoogloea ramigera* Kruse emend. Butterfield. (Kruse, in Flüggé, Die Mikroorganismen, 3 Aufl., 1, 1896, 68; Butterfield, Public Health Reports, 50, 1935, 671; Culture No. 50, Wattie, Pub Health Reports, 57, 1942, 1519.)

Rods: 1 by 2 to 4 microns, with rounded ends. Non-spore-forming. Capsules present. Motile with a single long polar flagellum. Gram-negative.

Gelatin: No liquefaction.

Grows better in aerated liquid media.

Agar: Scant growth.

Indole not formed.

No  $H_2S$  produced.

No acid or gas from carbohydrates.

Nitrites not produced from nitrates.

Optimum pH 7.0 to 7.4.

Optimum temperature 28° to 30°C.

Good growth at 20° and at 37°C. Minimum temperature 4°C.

Strict aerobic.

Distinctive character. Oxidizes sewage.

Source: Isolated from activated sludge.

Habitat: Produces zoogloal masses in activated sludge.

## Genus II. *Xanthomonas* Dowson\*

(*Phytomonas* Bergey et al., Manual, 1st ed., 1923, 174; Dowson, Cent. f. Bakt., II Abt., 100, 1939, 187.)

Cells usually monotrichous, with yellow, water-insoluble pigment. Proteins are usually readily digested. Milk usually becomes alkaline. Hydrogen sulfide is produced. Asparagin is not sufficient as an only source of carbon and nitrogen. Acid is produced from mono- and disaccharides. Mostly plant pathogens causing necrosis. From *Gr. xanthus*, yellow; *monas*, a unit; *M. L. monad*.

The type species is *Xanthomonas hyacinthi* (Wakker) Dowson.

### Key to the species of genus *Xanthomonas*.

#### 1. Colonies yellow.

##### a. Gelatin liquefied.

##### b. Starch hydrolysis feeble.

##### c. Nitrites not produced from nitrates.

##### 1. *Xanthomonas hyacinthi*.

##### 2. *Xanthomonas pruni*.

##### 3. *Xanthomonas vitians*.

\* Prepared by Prof. Walter H. Burkholder, Cornell Univ., Ithaca, N. Y., June, 1943.

cc. Nitrites produced from nitrates.

- 4 *Xanthomonas beticola*.
5. *Xanthomonas lactucae-scariolae*.
- 6 *Xanthomonas rubrifluens*

bb. Starch hydrolysis strong

c. Nitrites not produced from nitrates.

d No brown pigment in beef-extract agar.

- 7 *Xanthomonas barbarae*.
- 8 *Xanthomonas begoniae*.
- 9 *Xanthomonas campestris*.
- 9a *Xanthomonas campestris* var. *armoraciae*
10. *Xanthomonas citri*.
- 11 *Xanthomonas corylina*.
- 12 *Xanthomonas cucurbitae*.
- 13 *Xanthomonas dieffenbachiae*.
- 14 *Xanthomonas holcicola*.
- 15 *Xanthomonas incanae*.
- 16 *Xanthomonas juglandis*.
- 17 *Xanthomonas lespedezae*.
- 18 *Xanthomonas malvacearum*.
- 19 *Xanthomonas pelargonii*.
- 20 *Xanthomonas phaseoli* var. *soyense*
- 20a *Xanthomonas phaseoli* var. *soyense*
21. *Xanthomonas plantaginis*.
- 22 *Xanthomonas ricinicola*
- 23a *Xanthomonas translucens* f sp *hordei*
- 23b *Xanthomonas translucens* f sp *undulosa*.
- 23c *Xanthomonas translucens* f sp *secolis*.
- 23d *Xanthomonas translucens* f sp *hordei-arenae*
- 23e *Xanthomonas translucens* f sp *cerealis*
- 24 *Xanthomonas vasculorum*
- 25 *Xanthomonas vesicatoria*
- 25a *Xanthomonas vesicatoria* var *raphani*

dd Brown pigment produced in beef-extract media.

26 *Xanthomonas nakatae*

20b *Xanthomonas phaseoli* var *fusca*

cc. Nitrites produced from nitrates

27 *Xanthomonas papavericola*

ccc. Ammonia formed in nitrate media

28 *Xanthomonas alfalfae*

bbb. Starch not hydrolyzed

c Nitrites produced from nitrates

29 *Xanthomonas aceris*

cc Nitrites not produced from nitrates

30 *Xanthomonas carotae*

31. *Xanthomonas heliae*

32 *Xanthomonas phormicola*

25 *Xanthomonas vesicatoria*

ccc Ammonia formed in nitrate media

33. *Xanthomonas geranii*

bbbb. Starch hydrolysis not reported.

c. Nitrites produced from nitrates.

34. *Xanthomonas antirrhini*.

35. *Xanthomonas helerocea*.

cc. Nitrites not produced from nitrates.

36. *Xanthomonas gummisudans*.

37. *Xanthomonas lactucae*.

38. *Xanthomonas nigromaculans*.

aa. Gelatin not liquefied.

b. Starch not hydrolyzed.

39. *Xanthomonas oryzae*.

aaa. Gelatin not reported.

b. Starch hydrolyzed.

40. *Xanthomonas celebensis*.

2. Colonies whitish to cream.

a. Gelatin liquefied.

b. Starch hydrolyzed.

c. Nitrites produced from nitrates.

41. *Xanthomonas panici*.

42. *Xanthomonas proteomaculans*.

43. *Xanthomonas manihotis*.

cc. Nitrites not reported.

44. *Xanthomonas rubrisubalbicans*.

bb. Starch not reported.

45. *Xanthomonas cannae*.

46. *Xanthomonas zingiberi*.

47. *Xanthomonas conjaci*.

1. *Xanthomonas hyacinthi* (Wakker) Dowson. (*Bacterium hyacinthi* Wakker, Botan. Centralblatt, 14, 1883, 315; *Bacillus hyacinthi* Trevisan, I generi e le specie delle Batteriacee, 1889; 19; *Pseudomonas hyacinthi* Erw Smith, Bot. Gazette, 24, 1897, 188; *Phytomonas hyacinthi* Bergey et al., Manual, 1st ed., 1923, 177; Dowson, Cent. f. Bakt., II Abt., 100, 1939, 188.) From *Gr. hyacinthus*, the hyacinth; *M. L. Hyacinthus*, a generic name.

Description from Smith, Div. Veg. Phys and Path., U. S. D. A. Bul. 26, 1901, 40.

Rods 0.4 to 0.6 by 0.8 to 2 microns. Motile with a polar flagellum. Filaments present. Gram-negative.

Gelatin: Slow liquefaction.

Agar colonies: Circular, flat, moist, shining, bright yellow. Media stained brown.

Milk: Casein is precipitated and digested. Tyrosine crystals produced.

Nitrites not produced from nitrates

Indole: Slight production.

Hydrogen sulfide is produced.

Acid, no gas, from glucose, fructose, galactose, sucrose and maltose.

Starch: Hydrolysis slight.

Optimum temperature 28° to 30°C.

Maximum 34° to 35°C. Minimum 4°C.

Aerobic, with the exception of maltose, where it is facultative anaerobic.

Habitat: Produces a yellow rot of hyacinth bulbs, *Hyacinthus orientalis*.

2. *Xanthomonas pruni* (Erw. Smith)

Dowson. (*Pseudomonas pruni* Erw. Smith, Science, N. S. 17, 1903, 456;

*Bacterium pruni* Erw. Smith, Bacteria in

Relation to Plant Dis., 1, 1905, 171;

*Bacillus pruni* Holland, Jour. Bact., 5,

1920, 220; *Phytomonas pruni* Bergey et

al., Manual, 1st ed., 1923, 179; Dowson, Cent. J. Bakt., II Abt., 100, 1939, 190) From *L. prunus*, plum; *M. L. Prunus*, a generic name.

Probable synonym: *Phytomonas cerasi wraggi* Sackett, Col. Agr. Exp. Sta. Rept., 28, 1925, 17; *Pseudomonas cerasi wraggi*, *ibid.*; *Bacterium cerasi wraggi* Elliott, Bact. Plant Pathogens, 1930, 111.

Description from Dunegan, U. S. Dept. Agr., Tech. Bull. 273, 1932, 23

Rods: 0.2 to 0.4 by 0.8 to 1.0 microns. Capsules. Motile with a polar flagellum. Gram-negative.

Gelatin: Liquefaction

Beef-extract agar colonies: Yellow, circular, smooth, convex, edges entire. Broth: Turbid becoming viscid.

Milk: Precipitation of casein and digestion.

Nitrites not produced from nitrates. Indole not formed.

Hydrogen sulfide not produced. Hydrogen sulfide produced (Burkholder).

Lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 600).

Acid from arabinose, xylose, glucose, fructose, galactose, mannose, maltose, lactose, sucrose, raffinose, melzitose.

Starch is hydrolyzed (slight).

Aerobic.

Optimum temperature 21° to 29°C.

Maximum 37°C.

Source: Smith isolated the pathogen from Japanese plums.

Habitat: Pathogenic on plum (*Prunus salicina*), peach (*P. persica*), apricot (*P. armeniaca*), etc.

3. *Xanthomonas vitians* (Brown) Starr and Weiss (*Bacterium vitians* Brown, Jour. Agr. Res., 15, 1918, 379; *Phytomonas vitians* Bergey et al., Manual, 1st ed., 1923, 183; *Pseudomonas vitians* Stapp, in Soraue, Handb. d. Pflanzenkrank., 2, 5 Aufl., 1928, 287; Starr and Weiss, Phytopath., 33, 1943, 316) From Latin, *vitians*, injuring, infecting.

Rods: Motile with bipolar flagella. Gram-negative.

Gelatin: Slow liquefaction.

Beef-extract agar colonies: Circular, smooth, thin, cream to cream-yellow.

Broth: Turbid with yellow ring.

Milk: Clears and turns alkaline.

Nitrites not produced from nitrates.

Indole: Feeble production.

Hydrogen sulfide: Feeble production.

Acid but not gas from glucose.

Starch: Feeble hydrolysis.

Optimum temperature 26° to 25°C.

Maximum 35°C. Minimum 0°C.

Aerobic.

Source: Isolated from the stem of diseased lettuce plants from South Carolina.

Habitat: Pathogenic on lettuce, *Lactuca sativa*.

4. *Xanthomonas beticola* (Smith, Brown and Townsend) comb. nov. (*Bacterium beticolum* Smith, Brown and Townsend, U. S. Dept. Agr., Bur. Plant Ind., Bul. 213, 1911, 191; *Pseudomonas beticola* Holland, Jour. Bact., 5, 1920, 224; *Phytomonas beticola* Bergey et al., Manual, 1st ed., 1923, 182) From Latin, *beta*, beet, *-cola*, dweller.

Description from Brown, Jour. Agr. Res., 37, 1923, 167, where the species is referred to as *Bacterium beticola* (Smith, Brown and Townsend) Potebnia.

Rods: 0.4 to 0.8 by 0.6 to 2.0 microns. Motile with 1 to 4 polar flagella. Capsules Gram-variable.

Gelatin: Liquefaction.

Beef-agar slants: Moderate filiform growth, flat, glistening, yellow.

Broth: Turbid, yellow ring, abundant sediment.

Milk: Coagulation and peptonization.

Indole not formed.

Hydrogen sulfide formed.

Nitrites produced from nitrates.

Acid from glucose, sucrose, maltose, mannitol. No acid from lactose.

Starch hydrolysis feeble.

Optimum temperature 22°C. Maximum 39°C. Minimum 1.5°C.

Optimum pH 6.5. Maximum 9.0 to 9.5. Minimum 4.5 to 4.8.

Tolerates salt up to 9 per cent.

Aerobic.

Source: Isolated from galls on sugar beets collected in Colorado, Kansas, and Virginia.

Habitat: Produces gall on sugar beets and on garden beets.

NOTE: It is doubtful whether this species belongs in this genus

5. *Xanthomonas lactucae-scariorae* (Thornberry and Anderson) *comb. nov.* (*Phytomonas lactucae-scariorae* Thornberry and Anderson, *Phytopath.*, 27, 1937, 109.) From *Lactuca scariola*, the host.

Rods 0.5 to 1.0 by 1.0 to 1.5 microns. Motile with 1 or 2 polar flagella. Chains present. Capsules Gram-negative.

Gelatin: Slow liquefaction.

Glucose agar colonies: Round, entire, finely granular, amber yellow.

Broth: Turbid. No pellicle. A yellow rim.

Milk: Slight acid, and peptonization.

Nitrites are produced from nitrates.

Hydrogen sulfide not formed.

No gas from carbon sources.

Starch: Slight diastatic activity.

Optimum temperature 25°C. Maximum 35°C. Minimum 7°C.

Aerobic.

Source: Isolated from necrotic lesions on wild lettuce.

Habitat: Pathogenic on wild lettuce, *Lactuca scariola*, but not on cultivated lettuce, *Lactuca sativa*.

6. *Xanthomonas rubrilineans* (Lee et al.) Starr and Burkholder. (*Phytomonas rubrilineans* Lee, Purdy, Barnum and Martin, Hawaiian Sugar Planters' Assoc. Bull., 1925, 25; *Pseudomonas rubrilineans* Stapp, in Sorauer, Handb. d. Pflanzenkrank., 2, 5 Aufl., 1928, 35; *Bacterium rubrilineans* Elliott, Man. Bact. Plant Path., 1930, 195; Starr and Burkholder, *Phytopath.*, 32, 1942, 600.) From *L. ruber*, red; *lineans*, striping

Rods: 0.7 by 1.67 microns. Motile with 1 or seldom more polar flagella. Gram-negative.

Gelatin: Liquefaction.

Agar (Beef-extract + glucose) colonies: Small, smooth, glistening, buff to yellow.

Broth: Turbid with pellicle. Sediment.

Milk: Casein precipitated and digested.

Nitrites are produced from nitrates. Indole not produced.

Hydrogen sulfide not formed.

Not lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 600).

Acid from glucose, fructose, arabinose, xylose, lactose, sucrose, raffinose and mannitol.

Starch: Slight hydrolysis.

Growth range, pH 5.4 to pH 7.3.

Facultative anaerobe.

Source: Description from 3 cultures isolated from the red stripe lesions in sugar cane.

Habitat: Pathogenic on sugar cane.

7. *Xanthomonas barbareae* Burkholder. (Burkholder, *Phytopath.*, 31, 1941, 348. *Phytomonas barbareae* Burkholder, *ibid.*) From *M. L. Barbarea*, a generic name.

Rods: 0.4 to 0.95 by 1.0 to 3.15 microns. Motile with a single polar flagellum. Gram-negative.

Gelatin: Liquefaction.

Beef-extract peptone colonies: Circular, yellow, smooth, butyrous, growth moderate.

Potato glucose agar: Growth abundant, pale yellow. Mucoid.

Broth: Turbid, yellow granular ring. Milk: Soft curd, with clearing and production of tyrosine crystals. Litmus reduced.

Nitrates utilized but no nitrites formed. Asparagine and nitrites not utilized.

Hydrogen sulfide produced.

Indole not formed.

Lipolytic (Starr and Burkholder, *loc. cit.*).

Acid from glucose, galactose, xylose, maltose, sucrose, and glycerol. Alkali

produced from salts of malonic, citric, malic, and succinic acids. Rhamnose, salicin and hippuric acid salts not utilized.

Starch hydrolyzed.

Aerobic.

Distinctive characters Similar to *Xanthomonas campestris* but does not infect cabbage, cauliflower or horseradish

Source: From black rot of winter cress, *Barbarea vulgaris*.

Habitat: Pathogenic on leaves and stems of *Barbarea vulgaris*

8. *Xanthomonas begoniae* (Takimoto) Dowson. (*Bacterium begoniae* Takimoto, Jour. Plant. Protect., 21, 1934, 262, *Pseudomonas begoniae* Stapp, Arbeiten Biol. Reichsanst. f. Land- und Forstw., 22, 1935, 392; *Phytomonas begoniae* Burkholder, in Manual, 5th ed., 1939, 162, Dowson, Cent. f. Bakt., II Abt., 100, 1939, 190.) From *M. L. Begonia*, a generic name

Probable synonyms: *Bacterium begoniae* Buchwald nom. nud., Gartner-Tidende, 45, 1933, 1; *Phytomonas flava begoniae* Wieringa, Tidschr. Plantziekt., 41, 1935, 312; *Bacterium flarozonata* McCulloch, Jour. Agr. Res., 64, 1937, 859 (*Xanthomonas flarozonatum* Dowson, loc. cit.).

Translated by Dr. K. Togashi

Rods: 0.5 to 0.6 by 1.2 to 2.0 microns  
Motile with a polar flagellum Gram-negative.

Gelatin: No liquefaction Liquefaction (Wieringa, loc. cit., McCulloch, loc. cit., Dowson, loc. cit., and Stapp, loc. cit.).

Potato agar colonies Circular, convex, smooth, moist, shining, yellow

Broth: Turbid. Yellow pellicle and precipitation.

Milk: No coagulation. Casein digested Alkaline

Nitrites not produced from nitrates

Indole not produced

Hydrogen sulfide produced

Lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 600)

Starch hydrolyzed (Dowson, Jour. Roy. Hort. Soc., 63, 1938, 289)

No acid organs in peptone broth from glucose, sucrose, lactose or glycerol Acid from glucose, sucrose, lactose, mannitol and glycerol in peptone-free medium (McCulloch, loc. cit.).

Optimum temperature 27°C. Maximum 37°C. Minimum 1° to 3°C.

Source Isolated from leaf spot of begonia.

Habitat Pathogenic on *Begonia* spp.

9. *Xanthomonas campestris* (Pammel) Dowson. (*Bacillus campestris* Pammel, Iowa Agr. Exp. Sta. Bull. 27, 1895, 130, *Pseudomonas campestris* Erw. Smith, Cent. f. Bakt., II Abt., 3, 1897, 284, *Bacterium campestris* (sic) Chester, Del. Col. Agr. Exp. Sta. Ann. Rept., 9, 1897, 110, *Phytomonas campestris* Bergey et al., Manual, 1st ed., 1923, 176, Dowson, Cent. f. Bakt., II Abt., 100, 1939, 190) From *L. campestris* of the field

Description from McCulloch (Jour. Agr. Res., 53, 1929, 278) Species is probably composed of several varieties. See descriptions by Mekta, Ann. Appl. Biol., 12, 1925, 330, Paine and Nirula, Ann. Appl. Biol., 15, 1928, 46, Wormald and Frampton, Ann. Rept. East Mall Res. Sta., 1926 and 1927, II Supplement, 1928, 108, and others

Rods 0.3 to 0.5 by 0.7 to 2.0 microns  
Motile with a polar flagellum Capsules. Gram-negative.

Gelatin Liquefied

Beef agar colonies Wax yellow, round, smooth, shining, translucent, margins entire

Broth Turbid with yellow rim and sometimes a pellicle

Milk Casein digested with the formation of tyrosine crystals Alkaline

Nitrites not produced from nitrates

Indole formation weak

Hydrogen sulfide produced

Lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 600)

Acid, no gas, from glucose, sucrose, lactose, glycerol and mannitol.

Starch is hydrolyzed.

Optimum temperature 28° to 30°C.

Maximum 36°C.

Aerobic.

Distinctive characters: Causes a vascular infection in cabbage, cauliflower and rutabagas.

Source: Pammel (*loc. cit.*) first isolated the pathogen from diseased rutabagas.

Habitat: Pathogenic on cabbage, cauliflower and other related species.

9a. *Xanthomonas campestris* var. *armoraciae* (McCulloch) Burkholder. (*Bacterium campestre* var. *armoraciae* McCulloch, Jour. Agr. Res., 38, 1929, 269; *Phytomonas campestris* var. *armoraciae* Bergey et al., Manual, 3rd ed., 1930, 251; Burkholder, Phytopath., 32, 1942, 601) From Gr. *Armoracia*, the horse radish.

Cultural characters same as *Xanthomonas campestris*.

Distinctive characters: Causes a leaf spot of horse radish. No vascular infection.

Source: Isolated from diseased horse-radish leaves collected in Washington, D. C., Virginia, Connecticut, Iowa and Missouri.

Habitat: Pathogenic on horse radish and related species.

10 *Xanthomonas citri* (Hasse) Dowson (*Pseudomonas citri* Hasse, Jour. Agr. Res., 4, 1915, 97; *Bacterium citri* Doidge, Union So. Africa, Dept. Agr. Sci. Bul. 8, 1916, 20; *Bacillus citri* Holland, Jour. Bact., 5, 1920, 218; *Phytomonas citri* Bergey et al., Manual, 1st ed., 1923, 181; Dowson, Cent. f. Bakt., II Abt., 100, 1939, 190.) From M. L. *Citrus*, a generic name.

Rods: 0.5 to 0.75 by 1.5 to 2 microns, occurring in chains. Motile with a single polar flagellum. Gram-negative.

Gelatin Liquefied.

Beef agar colonies: Appear in 36-48 hours, circular, smooth, raised, dull yellow.

Broth: Turbid in 24 hours. A yellow ring formed.

Milk: Casein is precipitated.

Nitrites not produced from nitrates.

Hydrogen sulfide produced (Reid, New Zealand Jour. Sci. and Tech., 22, 1938, 60).

Indole not formed.

No gas from glucose, lactose or mannitol.

Starch hydrolyzed (Reid, *loc. cit.*).

Aerobic.

Optimum temperature, 25° to 34°C.

Maximum 38°C. Minimum 10°C. (Okabe, Jour. Soc. Trop. Agr., 4, 1932, 476).

Source: Isolated from canker on orange.

Habitat: Produces a canker on many species of *Citrus* and related plants.

11. *Xanthomonas corylina* Miller, Bollen, Simmons, Gross, and Barss. (Miller et al., Phytopath., 30, 1940, 731; *Phytomonas corylina* Miller et al., *ibid.*) From Gr. *corylus*, the hazelnut; M. L. *corylina*, of the hazel nut.

Rods: 0.5 to 0.7 by 1.1 to 3.8 microns. Motile with a polar flagellum. Capsules Gram-negative.

Gelatin: Liquefaction.

Nutrient glucose-agar streaks: Abundant growth, filiform, convex, glistening, smooth, opaque, pale lemon yellow, viscid.

Broth: Turbid. Ring formed in 2-5 days.

Milk: Enzymatic curd that is slowly digested. Litmus reduced. Crystal formation (Burkholder).

Nitrites not produced from nitrates.

Nitrogen sources utilized are peptone, aspartic acid, alanine, leucine, sodium ammonium phosphate, allantoin, tyrosine, uric acid and brucine.

Indole is not produced.

Hydrogen sulfide not produced on lead acetate agar. H<sub>2</sub>S produced after Zobell and Feltham's method (Burkholder).

Selenium dioxide reduced.

Lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 600).

Acid, no gas from glucose, fructose, galactose, lactose, sucrose, maltose, xylose, raffinose, mannitol, glycerol, and starch. Alkali from salts of citric, lactic,

malic and succinic acids. Arabinose, rhamnose, dulcitol, salicin, inulin, and cellulose not utilized.

Starch is hydrolyzed.

Optimum temperature 28° to 32°C. Maximum 37°C. Minimum 5° to 7°C. Thermal death point 53° to 55°C.

pH range for growth. pH 5.2 to 10.5.

Optimum pH 6 to 8.

Strict aerobe.

Distinctive characters: Cultural characters the same or similar to *Xanthomonas juglandis*. The two species do not cross-infect.

Source: 26 isolates from widely scattered filbert orchards in Oregon and Washington.

Habitat: Pathogenic on filberts (*Corylus avellana* and *C. maxima*).

#### 12 *Xanthomonas cucurbitae* (Bryan)

Dowson. (*Bacterium cucurbitae* Bryan, Science, 63, 1926, 165, Bryan, Jour. Agr. Res., 40, 1930, 350; *Phytomonas cucurbitae* Bergey et al., Manual, 3rd ed., 1930, 251; *Pseudomonas cucurbitae* Stapp, Bot. Rev., 1, 1935, 403; Dowson, Cent. f. Bakt., II Abt., 100, 1939, 190.) From *L. cucurbita*, a gourd, M. L. *Cucurbita*, a generic name.

Rods: 0.45 to 0.6 by 0.5 to 1.3 microns. Motile, usually with a single polar flagellum. Gram-negative.

Gelatin: Liquefied.

Beef-agar slants: Growth moderate, mustard yellow, undulating margins, viscid to butyrous.

Broth: Moderately turbid. Ring and yellow sediment.

Milk: Precipitation of casein and digestion. Alkaline.

Nitrites not produced from nitrates

Indole not formed.

Hydrogen sulfide produced

Acid from glucose, galactose, fructose, lactose, maltose, sucrose and glycerol. No acid from mannitol

Starch is hydrolyzed.

Optimum temperature 25° to 30°C. Maximum 35°C.

Optimum pH 6.5 to 7.0. Limits of growth pH 5.8 to 9.0.

Slight growth in 5 per cent salt.

Aerobic.

Source: Species first isolated from squash.

Habitat: Causes a leaf spot of squash and related plants.

13. *Xanthomonas dieffenbachiae* (McCulloch and Pirone) Dowson. (*Phytomonas dieffenbachiae* McCulloch and Pirone, Phytopath., 29, 1939, 962; *Bacterium dieffenbachiae* McCulloch and Pirone, *ibid.*; Dowson, Trans. Brit. Mycol. Soc., 26, 1943, 12.) From M. L. *Dieffenbachia*, a generic name.

Rods: 0.3 to 0.4 by 1.0 to 1.5 microns.

Motile with a single polar flagellum.

Capsules. Gram-negative.

Gelatin: Liquefied.

Beef-infusion peptone agar colonies: Slow growing, circular, flat, smooth, translucent. Butyrous. Massicot to Naples yellow.

Broth: Turbid. Yellow rim or slight pellicle.

Milk: Slow peptonization and formation of tyrosine crystals. Litmus reduced.

Nitrites not formed from nitrates

Indole not produced.

Hydrogen sulfide produced

Acid from glucose, sucrose, lactose, galactose, fructose and glycerol. Growth but no acid in maltose and mannitol.

Starch moderately hydrolyzed.

Optimum temperature 30° to 31°C.

Maximum 37° to 38°C. Minimum 5°C.

Aerobe.

Source: Seven isolates from diseased leaves of *Dieffenbachia picta*.

Habitat: Pathogenic on *Dieffenbachia picta*. Artificial infection of *Dracaena fragrans*.

14. *Xanthomonas holcicola* (Elliott) Starr and Burkholder. (*Bacterium holcicola* Elliott, Jour. Agr. Res., 40, 1930, 972; *Phytomonas holcicola* Bergoy et al., Manual, 4th ed., 1934, 271; *Pseudomonas*

Optimum temperature 25° to 30°C. Maximum 36° to 38°C. (Elliott, *loc. cit.*).

Source: Isolated from angular leaf spot of cotton.

Habitat: Pathogenic on cotton wherever it is grown, causing a leaf spot, a stem lesion and a boll lesion.

19. *Xanthomonas pelargonii* (Brown) Starr and Burkholder. (*Bacterium pelargonii* Brown, Jour. Agr. Res., 23, 1923, 372; *Pseudomonas pelargonii* Stapp, in Sorauer, Handb. d. Pflanzenkrank, 2, 5 Aufl., 1928, 181; *Phytomonas pelargonii* Bergey et al., Manual, 3rd ed., 1930, 250; Starr and Burkholder, Phytopath., 32, 1942, 600.) From Greek, *pelargus*, the stork; M. L. *Pelargonium*, a generic name for the stork's bill geranium.

Rods: 0.67 by 1.02 microns. Capsules. Motile with a polar flagellum. Gram-negative.

Gelatin: Slow liquefaction.

Beef-agar colonies: Cream-colored, glistening, round, with delicate internal markings.

Broth: Turbid in 24 hours. Incomplete pellicle.

Milk: Alkaline. Clearing in bands.

Nitrites not produced from nitrates

Indole formation slight.

Hydrogen sulfide produced.

Lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 600).

Slight acid but not gas from glucose, sucrose and glycerol.

Starch hydrolysis feebly positive.

Optimum temperature 27°C. Maximum 35°C.

No growth in broth plus 3.5 per cent salt.

Aerobic.

Source: Isolated from spots on leaves of *Pelargonium* from District of Columbia, Maryland and New Jersey.

Habitat: Pathogenic on *Pelargonium* spp. and *Geranium* spp.

20 *Xanthomonas phaseoli* (Erw. Smith) Dowson. (*Bacillus phaseoli* Erw. Smith, Bot. Gaz., 24, 1897, 192; A. A. A.

S. Proc., 46, 1898, 288; *Pseudomonas phaseoli* Erw. Smith, U. S. Dept. Agr., Div. Veg. Phys. and Path., Bul. 28, 1901, 1; *Bacterium phaseoli* Erw. Smith, Bact. in Rel. to Plant Dis., 1, 1905, 72; *Phytomonas phaseoli* Bergey et al., Manual, 1st ed., 1923, 177; Dowson, Cent. f. Bakt., II Abt., 100, 1939, 190.) From Gr. *phaseolus*, the bean; M. L. *Phaseolus*, a generic name.

Description from Burkholder, Cornell Agr. Exp. Sta. Mem. 127, 1930, 18; and Phytopath., 22, 1932, 609.

Rods: 0.87 by 1.0 microns. Motile with a polar flagellum. Gram-negative.

Gelatin: Liquefaction.

Beef-extract agar colonies: Circular, amber yellow, smooth, butyrous, edges entire.

Broth: Turbid in 24 hours. Yellow ring.

Milk: Casein precipitated and digested. Alkaline. Tyrosine crystals formed.

Nitrites not produced from nitrates.

Indole not formed.

Hydrogen sulfide produced.

Lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 600).

Acid but not gas from glucose, galactose, fructose, arabinose, xylose, maltose, lactose, sucrose, raffinose and glycerol. Alkaline reaction from salts of acetic, malic, citric and succinic acids. Mannitol, dulcitol, salicin and formic and tartaric acids not fermented.

Starch is hydrolyzed.

Aerobic.

Very slight growth in beef broth plus 4 per cent salt (Hedges, Jour. Agr. Res., 29, 1924, 243).

Distinctive character: Similar in culture to *Xanthomonas campestris*, *X. juglandis*, *X. vesicatoria*, etc., but they do not cross infect.

Habitat: Pathogenic on the bean (*Phaseolus vulgaris*), the hyacinth bean (*Dolichos lablab*), the lupine (*Lupinus polyphyllus*), etc. Not pathogenic on the soy bean (*Glycine* sp.), nor cowpea (*Vigna* sp.).

20a. *Xanthomonas phaseoli* var. *sojensis* (Hedges) Starr and Burkholder. (*Bacterium phaseoli* var. *sojense* Hedges, Science, 56, 1922, 11, Jour. Agr. Res., 29, 1921, 229; *Phytomonas phaseoli* var. *sojense* Burkholder, Phytopath., 20, 1930, 7; Starr and Burkholder, Phytopath., 32, 1942, 600) From M. L. the soy bean, *Soja*, a generic name, M. L. *sojensis*, of the soybean

Synonyms: *Pseudomonas glycines* Nakano, Jour. Plant Protect. Tokyo, 8, 1919, 39 (*Bacterium glycines* Elliott, Manual Bact. Plant Path., 1928, 133, *Phytomonas glycines* Magrou, in Hauduroy et al., Dict. d. Bact. Path., 1937, 358) (See Takimoto, Jour. Plant Protect. Tokyo, 18, 1931, 29; and Okabe, Jour. Trop. Agr. Formosa, 4, 1932, 473)

Distinctive character: Differs from *Xanthomonas phaseoli* in that it infects the soy bean, *Glycine max*.

Source: Isolated from pustules on the leaves and pods of soy bean, both in America and in Japan.

Habitat: Pathogenic on the soy bean, *Glycine max* and the common bean, *Phaseolus vulgaris*.

20b. *Xanthomonas phaseoli* var. *fuscans* (Burkholder) Starr and Burkholder (*Phytomonas phaseoli* var. *fuscans* Burkholder, Cornell Agr. Exp. Sta. Mem. 126, 1930, 22; Phytopath., 22, 1932, 699, *Bacterium phaseoli* var. *fuscans* Okabe, Jour. Soc. Trop. Agr. Formosa, 5, 1933, 161; *Pseudomonas phaseoli* var. *fuscans* Stapp, Bot. Rev., 1, 1935, 407; Starr and Burkholder, Phytopath., 32, 1942, 600) From L. *fuscans*, producing a brown color.

Distinctive characters: Differs from *Xanthomonas phaseoli* in that it produces a deep brown color in beef-extract-peptone media and in tyrosine media. Action on maltose negative or feeble.

Source: Two cultures isolated; one from a diseased bean leaf (1924) and a diseased pod (1927) collected in Switzerland.

Habitat: Pathogenic on beans, *Phaseolus vulgaris*, and related plants.

21. *Xanthomonas plantaginis* (Thornberry and Anderson) comb. nov. (*Phytomonas plantaginis* Thornberry and Anderson, Phytopath., 27, 1937, 947.) From Latin, *Plantago* (-aginis), plantain; M. L. *Plantago*, a generic name.

Rods: 0.6 to 1.0 by 1.0 to 1.8 microns. Occurring singly or in chains. Capsules. Motile with 1 to 2 polar flagella. Gram-negative.

Gelatin: Slight liquefaction.

Glucose agar slant: Growth moderate, filiform, raised, opaque, yellow and viscid.

Broth: Moderately turbid with ring.

Milk: Slight acidity, no reduction of litmus. Peptonization.

Nitrites not produced from nitrates.

Indole not formed

Hydrogen sulfide not produced.

No appreciable amount of gas from carbohydrates.

Starch is hydrolyzed

Optimum temperature 25°C. Minimum 12°C. Maximum 35°C. Thermal death point 50°C.

Aerobic

Source: From diseased leaves of *Plantago lanceolata* in Illinois.

Habitat: Pathogenic on *Plantago* spp.

22. *Xanthomonas ricinicola* (Elliott) Dowson (*Bacterium ricini* Yoshi and Takimoto, Jour. Plant Protect. Tokyo, 15, 1928, 12, *Bacterium ricinicola* Elliott, Man. Bact. Plant Path., 1930, 193; *Phytomonas ricinicola* Burkholder, in Manual, 5th ed., 1933, 152; Dowson, Cent. f. Bakt., II Abt., 100, 1939, 190, *Xanthomonas ricini* Dowson, *ibid.*) From L. living on the castor bean, M. L. *Ricinus*, a generic name.

Rods: 0.4 to 0.9 by 1.3 to 2.6 microns. Capsules. Short chains. Motile with polar flagella. Gram-negative

Gelatin: Liquefaction.

Nutrient agar colonies: Lemon yellow, changing to brown.

Milk: Slightly acid. No coagulation. Peptonization.

Nitrites not produced from nitrates.

Acid but not gas from lactose.

Starch hydrolyzed.

Optimum temperature 29° to 30°C.

Maximum 39°C. Minimum 2.5°C.

Aerobic.

Source: Isolated from leaf-spot of castor-bean.

Habitat: Pathogenic on *Ricinus communis*.

23a. *Xanthomonas translucens* f. sp. *hordei* Hagborg. (Canadian Jour. of Res., 20, 1942, 317.) From *L. translucens*, shining through, translucent, referring to the character of the lesion produced by this pathogen. Form name from *Hordeum*, a generic name.

Synonyms: *Bacterium translucens* Jones, Johnson and Reddy, Jour. Agr. Res., 11, 1917, 637; *Pseudomonas translucens*, *ibid.*; *Phytomonas translucens* Bergey et al, Manual, 3rd ed., 1930, 252; *Xanthomonas translucens* Dowson, Cent. f. Bakt., II Abt., 100, 1939, 190.

Rods: 0.5 to 0.8 by 1 to 2.5 microns. Motile with a single polar flagellum. Gram-negative.

Gelatin: Liquefaction

Beef-peptone agar colonies: Round, smooth, shining, amorphous except for inconspicuous somewhat irregular concentric striations within, wax-yellow tinged with old gold; margin entire.

Broth: Turbidity becomes rather strong. Pellicle.

Milk: Soft coagulum and digestion. Milk clears Tyrosine crystals produced.

Nitrites not produced from nitrates.

Indole: Slight formation.

Hydrogen sulfide produced.

Lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 600)

Ammonia from peptone.

Acid but not gas from glucose, d-fructose, d-mannose, d-galactose, sucrose, lactose, and sometimes salicin. No utilization of l-rhamnose, inositol, maltose,

raffinose, inulin, d-mannitol, and dulcitol.

Starch hydrolyzed.

Optimum temperature 26°C. Maximum 36°C. Minimum 6°C.

Aerobic.

Distinctive characters: All forms of *Xanthomonas translucens* have the same cultural characters. They differ mainly in pathogenicity. This form is pathogenic on barley, *Hordeum* spp.; but not on oats, *Avena* spp., rye, *Secale cereale* nor on wheat, *Triticum* spp.

Source: Isolated from leaves and seed of barley, *Hordeum vulgare*.

Habitat: Occurs naturally on barley.

23b. *Xanthomonas translucens* f. sp. *undulosa* (Smith, Jones and Reddy) Hagborg. (*Bacterium translucens* var. *undulosum* Smith, Jones and Reddy, Science, 50, 1919, 48; *Pseudomonas translucens* var. *undulosa* Stapp, in Sorauer, Handb. d. Pflanzenk., 2, 5 Aufl., 1928, 17; *Phytomonas translucens* var. *undulosa* Hagborg, Canadian Jour. Res., 14, 1936, 347; Hagborg, Canadian Jour. Res., 20, 1942, 317.) From *L. unda*; M.L. *undulosus*, undulate, referring to the undulation of the colony.

Distinctive characters: Cultural characters same as all forms of *Xanthomonas translucens*. Pathogenic on wheat, *Triticum* spp., barley, *Hordeum* spp. and rye, *Secale cereale* but not on oats, *Avena* spp.

Source: Isolated repeatedly from black chaff of wheat.

Habitat: Usually found on wheat causing the black chaff, and on rye.

23c. *Xanthomonas translucens* f. sp. *secalis* (Reddy, Godkin and Johnson) Hagborg. (*Bacterium translucens* var. *secalis* Reddy, Godkin and Johnson, Jour. Agr. Res., 28, 1924, 1039; *Pseudomonas translucens* var. *secalis* Stapp, in Sorauer, Handb. d. Pflanzenk., 2, 5 Aufl., 1928, 24; *Phytomonas translucens* var. *secalis* Burkholder, in Manual, 5th ed., 1939, 160; Hagborg, Canadian Jour.

Res., 20, 1942, 317.) From M.L. *Secale*, a generic name. Distinctive characters Cultural characters same as other forms of *Xanthomonas translucens*. This form pathogenic on rye *Secale cereale*, but not on *Triticum* spp., *Hordeum* spp. nor *Avena* spp.

Source: Isolated from leaf spot on rye, *Secale cereale*.

Habitat: Pathogenic on rye.

23d. *Xanthomonas translucens* f. sp. *hordei-avenae* Hagborg (Canadian Jour Res, 20, 1942, 317.) From M L *Hordeum* and *Avena*, generic names.

Distinctive characters Cultural characters same as other forms of *Xanthomonas translucens*. Pathogenic on barley, *Hordeum* spp and oats, *Avena* spp, but not on wheat, *Triticum* spp, nor rye, *Secale cereale*.

Source: Isolated 6 times from barley at various places in Canada

Habitat: Occurs naturally on barley

23e. *Xanthomonas translucens* f sp. *cerealis* Hagborg. (Canadian Jour Res, 20, 1942, 317.) From L., of cereal.

Distinctive characters: Cultural characters same as other forms of *Xanthomonas translucens*. Pathogenic on wheat, *Triticum* spp.; oats, *Avena* spp.; barley, *Hordeum* spp.; and rye, *Secale cereale*

Source: Isolated from wheat in Canada.

Habitat: Occurs naturally on wheat.

24. *Xanthomonas vascularum* (Cobb) Dowson. (*Bacillus vascularum* (sic) Cobb, Agr. Gaz. of New South Wales, 4, 1893, 777; Abst. in Cent. f. Bakt., II Abt, 1, 1895, 41; *Bacterium vascularum* Migula, Syst. d. Bakt., 2, 1900, 512, *Pseudomonas vascularum* Erw. Smith, U. S. Dept Agr, Div. Veg. Phys and Path, Bul 28, 1901, 153; *Phytomonas vascularum* Bergey et al., Manual, 1st ed, 1923, 179; Dowson, Cent. f. Bakt., II Abt, 100, 1939, 190.) From L. *vasculum*, a small vessel; M. L. the vascular system.

NOTE: Erw. Smith (Bact. in Rel. to

Plant Dis., 5, 1914, 88) states that probably Spegazzini (El Polville de la Canna de Azucar, June, 1895, La Plata, Supl. Rev. Azuc., Buenos Aires, No 16, 1895) reported the disease caused by *Xanthomonas vascularum* but that *Bacillus sacchari* Spegazzini which he claimed to be the pathogen, was a saprophyte

Description from Smith (loc. cit., 54).

Rods: 0.4 by 1.0 microns Motile with a polar flagellum. Gram-variable.

Gelatin: Liquefaction feeble. Liquefaction good (Burkholder).

Beef-extract agar colonies Pale yellow, smooth, glistening, not noticeably viscid.

Broth. Good growth.

Milk: Alkaline

Nitrites not produced from nitrates.

Lipolytic (Starr and Burkholder, Phytopath, 32, 1942, 600).

Acid but not gas from glucose, fructose and glycerol.

Starch hydrolyzed (Burkholder).

Optimum temperature 30°C. Maximum 35° to 37.5°C (Elliott, loc cit).

Habitat. Pathogenic on sugar cane, *Saccharum officinarum*, causing a bacterial gummosis.

25 *Xanthomonas vesicatoria* (Doidge) Dowson. (*Bacterium vesicatorium* Doidge, Jour Dept Agr, S Africa, 1, 1920, 718, also Ann Appl. Biol, 7, 1921, 428, *Pseudomonas vesicatoria* Stapp, in Sorauer, Handb d Pflanzenkrank., 2, 5 Aufl., 1928, 239, *Phytomonas vesicatoria* Bergey et al, Manual, 3rd ed, 1930, 253; Dowson, Cent f Bakt, II Abt., 100, 1939, 190 ) From L. *vesica*, a blister; M. L. *vesicatorius*, causing blisters.

Synonyms: Gardner and Kendrick (Phytopath, 13, 1923, 307) list *Pseudomonas exilis* Gardner and Kendrick (Phytopath, 11, 1921, 55; *Bacterium exitosum* Gardner and Kendrick, Jour. Agr. Res., 21, 1921, 141; *Phytomonas exilis* Bergey et al., Manual, 1st ed., 1923, 183) and an unnamed species, Higgins (Phytopath, 12, 1922, 513).

Rods: 0.6 to 0.7 by 1.0 to 1.5 microns

Motile with a polar flagellum. Capsules. Gram-positive. Gram-negative (Gardner and Kendrick; and Higgins).

Gelatin: Liquefaction.

Nutrient agar colonies: Good growth. Circular, wet-shining, Naples yellow, edges entire.

Milk: Casein precipitated and slowly digested. Tyrosine crystals.

Nitrites not produced from nitrates.

Indole not formed.

Hydrogen sulfide produced (Burkholder).

Lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 600).

Acid but not gas from glucose, fructose, sucrose, lactose, galactose, glycerol and dextrin.

Certain strains hydrolyze starch, others do not (Burkholder and Li, *Phytopath.*, 31, 1941, 753).

Optimum temperature 30°C.

Source: Isolated from spotted tomato fruits in South Africa.

Habitat: Pathogen on tomatoes, *Lycopersicon esculentum* and peppers, *Capsicum annum*.

25a. *Xanthomonas vesicatoria* var. *raphani* (White) Starr and Burkholder. (*Bacterium vesicatoria* var. *raphani* White, *Phytopath.*, 20, 1930, 653; *Phytomonas vesicatoria* var. *raphani* Burkholder, in Manual, 5th ed., 1939, 154; Starr and Burkholder, *Phytopath.*, 32, 1942, 600.) From *M. L. Raphanus*, the radish, a generic name.

Distinctive characters: Cultural characters similar to *Xanthomonas vesicatoria*, but differs in that it is able to attack radishes, turnips, and other crucifers. Differs from *Xanthomonas campestris* in that it does not cause a vascular disease, and differs from *Xanthomonas campestris* var. *armoraciae* in that it is not pathogenic on horseradish.

Source: Isolated from leaf spots of radish and turnips in Indiana.

Habitat: Pathogenic on radish, turnips, and other crucifers; and on tomato and pepper.

26. *Xanthomonas nakatae* (Okabe) Dowson. (*Bacterium nakatae* Type B, Okabe, *Jour. Soc. Trop. Agr.*, Formosa, 5, 1933, 161; *Phytomonas nakatae* Burkholder, in Manual, 5th ed., 1939, 154; Dowson, *Trans. Brit. Mycol. Soc.*, 26, 1943, 12.) Named for Nakata, the Japanese plant pathologist.

Rods: 0.3 to 0.4 by 1.1 to 2.5 microns. Capsules. Motile with a polar flagellum. Gram-negative.

Gelatin: Liquefaction. Brown color.

Beef-extract agar colonies: Amber yellow, round, smooth, glistening, margins entire. Brown.

Broth: Moderate turbidity with yellow ring. Medium turns brown.

Milk: Casein is precipitated and digested. Tyrosine crystals. Brown color.

Nitrites not produced from nitrates.

Indole not formed.

Slight amount H<sub>2</sub>S produced.

Acid but not gas from glucose, sucrose, maltose and lactose.

Starch: Strong diastatic action.

Optimum temperature 30° to 32°C.

Maximum 39°C. Minimum 10°C.

No growth in beef extract broth plus 2 per cent salt.

Aerobic.

Distinctive character: Differs from Type A in that it produces a brown pigment in culture. (Description of Type A not seen.)

Source: Isolated from water-soaked to brown leaf spots on jute.

Habitat: Pathogenic on jute, *Corchorus capsularis*.

27. *Xanthomonas papavericola* (Bryan and McWhorter) Dowson. (*Bacterium papavericola* Bryan and McWhorter, *Jour. Agr. Res.*, 40, 1930, 9; *Phytomonas papavericola* Bergey et al., Manual, 4th ed., 1934, 266; Dowson, *Cent. f. Bakt.*, II Abt., 100, 1939, 190.) From *L. papaver*, poppy, -cola, dweller; *M. L. Papaver*, a generic name.

Rods: 0.6 to 0.7 by 1 to 1.7 microns. Chains. Capsules. Motile with a single polar flagellum. Gram-negative.

Gelatin: Liquefaction.

Beef agar colonies: Mustard yellow to primuline yellow, circular, margins entire.

Broth: Turbidity prompt with a yellow ring and an incomplete pellicle.

Milk: Soft coagulation, peptonization and production of tyrosine crystals

Nitrates: A weak reaction for nitrites after 10 days.

Indole not formed.

Hydrogen sulfide is produced.

Lipolytic (Starr and Burkholder, Phytopath., 32, 1942, 600).

Acid but not gas from glucose, galactose, fructose, sucrose, lactose, maltose, glycerol and mannitol.

Starch is hydrolyzed

Optimum temperature 25° to 30°C. Maximum 35°C.

No growth in broth plus 5 per cent salt.

Aerobic.

Source: Isolated from black spots on leaves, buds and pods of poppy

Habitat: Pathogenic on poppy, *Papaver rhoeas*.

28. *Xanthomonas alfalfae* (Riker et al.) Dowson. (*Bacterium alfalfae* Riker, Jones and Davis, Jour. Agr. Res., 51, 1935, 177; *Phytomonas alfalfae* Riker et al., *ibid.*; *Pseudomonas alfalfae* Riker et al., *ibid.*; Dowson, Trans. Brit. Mycol. Soc., 26, 1943, 11.) From Spanish, of alfalfa.

Rods: 0.45 by 2.4 microns. Motile with a polar flagellum. Gram-negative.

Gelatin: Liquefied.

Nutrient agar stroke: Growth abundant, filiform, smooth, glistening, butyrous, pale yellow.

Broth: Turbid in 24 hours. Light sediment.

Milk: Casein is precipitated and digested.

Ammonia formed slowly in a nitrate medium.

Carbohydrates: No acid in yeast broth plus sugars.

Starch is hydrolyzed

Aerobic.

Optimum temperature 24° to 32°C. Maximum below 36°C. Minimum below 4°C.

Source: Six single cell cultures isolated from diseased alfalfa.

Habitat: Pathogenic on the leaves of alfalfa, *Medicago sativa*.

29. *Xanthomonas acernea* (Ogawa) *comb. nov.* (*Pseudomonas acernea* Ogawa, Ann. Phyt. Soc. Japan, 7, 1937, 123; *Phytomonas acernea* Ark, Phytopath., 29, 1939, 968.) From *L. acerneus*, of the maple.

Rods: 0.2 to 0.6 by 0.5 to 1.2 microns. Motile with one polar flagellum. Gram-negative.

Gelatin: Liquefied.

Agar colonies: Round, smooth, convex, white to citron yellow, glistening, translucent with amorphous structure.

Broth: Turbid.

Milk: Slowly cleared, slightly acid. No coagulation.

Nitrites produced from nitrates.

Hydrogen sulfide produced.

No gas produced in peptone water plus sugars.

Starch not hydrolyzed

Optimum temperature about 32°C.

Thermal death point 59°C.

Aerobic.

Source: From diseased leaves of *Acer trifidum* in Japan.

Habitat: Causes a disease in *Acer* spp. and in *Aesculus turbinata* and *Koeleria paniculata*

30. *Xanthomonas carotae* (Kendrick) Dowson. (*Phytomonas carotae* Kendrick, Jour. Agr. Res., 49, 1934, 504; *Pseudomonas carotae* Kendrick, *ibid.*; Dowson, Cent. f. Bakt., II Abt., 100, 1939, 190.) From *L. carota*, the carrot.

Rods: 0.42 to 0.85 by 1.38 to 2.75 microns. Motile with 1 or 2 polar flagella. Gram-negative.

Gelatin: Liquefied.

Potato glucose agar: Colonies round, smooth, glistening, margins entire, straw yellow in color.

Milk: Casein precipitated and milk cleared; alkaline.

Nitrites not produced from nitrates.

Indole not formed.

Acid, no gas, from glucose, *d*-galactose, xylose, *d*-mannose, *l*-arabinose, sucrose, lactose, raffinose, trehalose, *d*-mannitol and glycerol. No acid from maltose and rhamnose.

Starch not hydrolyzed.

Optimum temperature 25° to 30°C.

Tolerates 4 per cent salt at pH 7

Aerobic.

Source Two original isolations from diseased carrots and a reisolation from inoculated carrots were used for the description.

Habitat. Pathogenic on leaves of *Daucus carota* var *sativa*.

31. *Xanthomonas hederae* (Arnaud) Dowson (*Bacterium hederae* Arnaud, Compt. rend Acad. Sci., Paris, 171, 1920, 121; *Phytomonas hederae* Burkholder and Guterman, Phytopath., 22, 1932, 783, Dowson, Cent. f. Bakt., II Abt., 100, 1939, 190) From *L. hedera*, ivy; M. L. *Hedera*, a generic name.

Description taken from Burkholder and Guterman (*loc. cit.*).

Rods: 0.6 by 2.13 microns. Motile with a single polar flagellum. Gram-negative.

Gelatin: Liquefied

Beef-extract-agar slants: Growth good, filiform, amber yellow, butyrous.

Broth: Turbid.

Milk: Casein is precipitated and digested. Milk becomes alkaline.

Nitrites not produced from nitrates.

Hydrogen sulfide is formed.

Indole not formed.

Not hypolytic (Starr and Burkholder, Phytopath., 32, 1942, 600)

Acid from glucose, fructose, galactose, xylose, sucrose, lactose and glycerol. Alkali from salts of acetic, citric, lactic, malic and succinic acids. The following are not utilized: arabinose, rhamnose, maltose, sahnin, starch, cellulose and formic acid.

Aerobic, facultative.

Source: Isolated from diseased ivy leaves.

Habitat: Pathogenic on ivy, *Hedera helix*.

32. *Xanthomonas phormicola* (Takimoto) Dowson (*Bacterium phormicola* Takimoto, Jour. Plant Protect., 20, 1933, 777; *Phytomonas phormicola* Burkholder, in Manual, 5th ed., 1939, 150; Dowson, Trans. Brit. Mycol. Soc., 26, 1943, 12.) From M. L. *Phormium*, a generic name.

Description translated by Dr. K. Togashi.

Rods: 0.5 to 0.6 by 1 to 2 microns. Motile, with a single flagellum. Gram-negative.

Gelatin: Liquefied.

Agar colonies: Light yellow, then waxy yellow; butyrous, then viscid.

Broth: Turbid, pellicle formed.

Milk: Casein coagulated slowly and precipitated, then digested. Alkaline.

Nitrites not produced from nitrates.

Indole not formed

Hydrogen sulfide produced.

No gas from sucrose, glucose, lactose and glycerol.

No acid from various sugars in broth.

Optimum temperature about 29°C. Maximum 39°C. Minimum about 0°C.

Aerobic.

Source: Species isolated from New Zealand flax, *Phormium tenax*.

Habitat: Causes a leaf stripe of *Phormium tenax*.

33. *Xanthomonas geranii* (Burkholder) Dowson. (*Phytomonas geranii* Burkholder, Phytopath., 27, 1937, 560; Dowson, Cent. f. Bakt., II Abt., 100, 1939, 190) From Greek, *geranos*, crane; M. L. *Geranium*, a generic name.

Rods: 0.75 to 2.0 microns. Motile with a single polar flagellum. Gram-negative

Gelatin: Liquefied.

Beef-extract agar slants: Moderate to good filiform growth, glistening, primuline yellow. Develops in 24 hours.

Broth: Turbid in 24 hours. No pellicle but a moderate sediment.

Milk: Becomes clear with a heavy casein precipitate. Peptonization with crystal formation.

Nitrates reduced to ammonia

Indole not formed.

Hydrogen sulfide formed

Lipolytic (Starr and Burkholder, *Phytopath.*, 32, 1942, 600).

Acid from glucose, galactose, fructose, xylose, rhamnose, lactose, sucrose, raffinose and glycerol. Alkaline reaction from salts of citric, malic, malonic and succinic acid. No growth in arabinose or formic, hippuric, maleic or tartaric acid.

Starch not hydrolyzed

Aerobe.

Distinctive characters Pathogenic on *Geranium* spp., not on the house geranium, *Pelargonium hortorum*. In culture similar to *Xanthomonas pelargonii*.

Source: Three cultures isolated from *Geranium sanguineum*.

Habitat: Pathogenic on *Geranium sanguineum*, *G. maculatum*, *G. pratense* and *G. sylvaticum*.

31 *Xanthomonas antirrhini* (Takimoto) Dowson. (*Pseudomonas antirrhini* Takimoto, Bot Mag Tokyo, 34, 1920, 257; *Bacterium antirrhini* Elliott, Man. Bact. Plant Path., 1930, 93, *Phytophthora antirrhini* Magrou, in Haudumy et al., Diet. d. bact. path., Paris, 1937, 331; Dowson, Trans Brit Mycol Soc., 26, 1943, 11.) From *Gr. antirrhinum*, snapdragon; *M. L. Antirrhinum*, a generic name.

Description from Elliott (loc. cit.)

Rods: 0.3 to 0.4 by 0.8 to 1.2 microns. Motile with polar flagella. Capsules Gram-negative.

Gelatin: Liquefied

Agar colonies: Round, glistening, white, later yellow.

Milk: Coagulated and casein digested.

Nitrites are produced from nitrates.

No gas produced.

Aerobic.

Optimum temperature 26° to 27°C. Maximum 34°C.

Habitat: Causes a leaf spot of *Antirrhinum majus*.

35. *Xanthomonas heterocea* (Vzoroff) comb. nov. (*Phytophthora heterocea* Vzoroff, Bull. North Caucasian Plant Prot. Sta. Rostoff-on-Don, 6-7, 1930, 263; *Bacterium heterocea* Burgwitz, Phytopathogenic bacteria, Leningrad, 1935, 135.) From *Gr. heterus*, another, different.

Description taken from Rev. App. Myc., 10, 1931, 628.

Rods: 0.4 to 0.6 by 1.0 to 2.0 microns.

Motile Gram-negative.

Gelatin: Slow liquefaction.

Agar colonies: Round, convex, smooth, semi-transparent, glistening, yellow to amber, 2 mm in diameter. Pitted surface.

Milk: No coagulation. At first acid, later alkaline.

Nitrites produced from nitrates.

Indole not formed.

Hydrogen sulfide produced.

Acid from glucose, galactose, arabinose, xylose, sucrose, maltose, salicin, glycerol and mannitol. Does not ferment lactose, inulin, ethyl alcohol, esculin, adonitol or dulcitol.

Optimum temperature 25° to 30°C.

Source: Isolated from diseased tobacco in the North Caucasus.

Habitat: Pathogenic on *Nicotiana glauca*.

36 *Xanthomonas gummisudans* (McCulloch) Starr and Burkholder. (*Bacterium gummisudans* McCulloch, *Phytopath.*, 14, 1924, 63, also *Jour. Agr. Res.*, 27, 1924, 229; *Pseudomonas gummisudans* Stapp, in Forauer, Handb. d. Pflanzenkrank., 2, 5. Aufl., 1928, 51; *Phytophthora gummisudans* Berkey et al., Manual, 2nd ed., 1925, 201; Starr and Burkholder, *Phytopath.*, 32, 1942, 600.) From *L. gummi*, gum; *sudans*, sweating, dripping.

Rods: 0.6 to 0.8 by 1 to 2.5 microns.

Capsules. Motile with a polar flagellum.  
Gram-negative.

Gelatin: Liquefied.

Beef-peptone agar colonies: Amber yellow, circular, transparent, smooth, with definite margins.

Broth: Moderately turbid with a yellow ring.

Milk: Soft curd which is digested with formation of tyrosine crystals.

Nitrites not produced from nitrates.

Indole not produced.

Hydrogen sulfide produced.

Lipolytic (Starr and Burkholder, *loc. cit.*).

Acid from glucose and sucrose.

Optimum temperature 30°C. Maximum 36°C. Minimum 2°C.

Aerobic.

Source: From gummy lesions on gladiolus leaves.

Habitat: Pathogenic on leaves of gladioli.

37. *Xanthomonas lactucae* (Yamamoto) Dowson. (*Bacterium lactucae* Yamamoto, Jour. Plant Protect., 21, 1934, 532; *Phytomonas lactucae* Bergey et al., Manual, 5th ed., 1939, 163; Dowson, Trans. Brit. Mycol. Soc., 26, 1943, 12.) From *L. lactuca*, lettuce; *M. L. Lactuca*, a generic name.

Description translated by Dr. K. Togashi.

Rods: 0.6 to 0.8 by 1.75 to 2.8 microns. Motile with a polar flagellum. Gram-negative.

Gelatin: Liquefaction slow.

Agar colonies: Circular, convex, margin entire, surface smooth, wet-shining, yellow.

Broth: Turbid. Ring and pellicle.

Milk: Slow peptonization.

Nitrites not produced from nitrates.

Indole not produced.

Hydrogen sulfide produced.

Acid, no gas, from glucose, sucrose, and lactose in bouillon; no acid from glycerol in bouillon.

Optimum temperature 28°C. Maximum 35°C. Minimum below 2°C.

Aerobic.

Source: Isolated from leaf spot of lettuce.

Habitat: Pathogenic on leaves of asparagus lettuce, *Lactuca sativa* var. *angustata*.

38. *Xanthomonas nigromaculans* (Takimoto) Dowson. (*Bacterium nigromaculans* Takimoto, Jour. Plant Protect., Tokyo, 14, 1927, 522; *Phytomonas nigromaculans* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 387; Dowson, Trans. Brit. Mycol. Soc., 26, 1943, 12.) From *L. niger*, black; *maculans*, spotting.

Description translated by Dr. K. Togashi.

Rods: 0.6 to 0.9 by 1.5 to 2.8 microns. Motile with 1 or 2 polar flagella. Gram-negative.

Gelatin: Liquefaction.

Agar colonies: Yellow, circular, margins entire, smooth, glistening.

Broth: Growth moderate with yellow pellicle.

Milk: Coagulation and digestion of the casein.

Nitrites not produced from nitrates.

Indole not produced.

No acid or gas from glucose, sucrose, lactose, mannitol and glycerol in peptone water.

Optimum temperature 27° to 28°C. Maximum 33°C. Minimum 0°C.

Aerobic.

Source: Isolated from lesions on leaf and petioles of burdock.

Habitat: Pathogenic on leaves and petioles of *Arctium lappa*, the burdock.

39. *Xanthomonas oryzae* (Uyeda and Ishiyama) Dowson. (*Pseudomonas oryzae* Uyeda and Ishiyama, Proc. Third Pan-Pacific Sci. Congr., Tokyo, 2, 1926, 2112; *Bacterium oryzae* Nakata, see Elliott, Man. Bact. Plant Path., 1930, 172; *Phytomonas oryzae* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 388; Dowson, Trans. Brit.

Mycol. Soc., 26, 1913, 12.) From *Gr. oryza*, rice; M. L. *Oryza*, a generic name

Probable synonym: *Pseudomonas itoana* Tochinai, Ann. Phytopath. Soc. Japan, 2, 1932, 456; *Bacterium itoanum* Burgwitz, Phytopathogenic Bacteria, Leningrad, 1935, 74; *Phytomonas itoana* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 370

Rods: 0.5 to 0.8 by 1.0 to 2.0 microns. Motile with a polar flagellum Gram-negative.

Gelatin: No liquefaction.

Nutrient agar colonies: Round, smooth, glistening, wax yellow.

Milk: Slightly acid.

Nitrites are not produced from nitrates.

Hydrogen sulfide produced.

Acid but no gas from glucose, lactose and sucrose.

Optimum temperature 26° to 30°C.

Strict aerobic.

Source: Isolated from a leaf blight of rice.

Habitat: Pathogenic on rice, *Oryza sativa*.

40. *Xanthomonas celebensis* (Gäumann) Dowson. (*Pseudomonas celebensis* Gäumann, Ztschr. f. Pflanzenkrank., 33, 1923, 11; Meded. Inst. voor Plantenziek., Buitenzorg, 59, 1923, 17; *Bacterium celebense* Elliott, Man. Bact. Plant Path., 1930, 103; *Phytomonas celebensis* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 343; Dowson, Trans. Brit. Mycol. Soc., 26, 1913, 11.) From M. L. of the island Celebes.

Rods: 0.9 by 1.5 microns. Motile by a polar flagellum. Gram-negative.

Agar colonies: Grayish yellow.

Broth: Thin pellicle.

Milk: Coagulated and cleared.

Nitrites not produced from nitrates.

Sodium selenite: Brick red

Starch is hydrolyzed.

Source: From vascular bundles of diseased bananas in Celebes.

Habitat: Causes the blood disease of banana.

41. *Xanthomonas panici* (Elliott) comb. nov. (*Bacterium panici* Elliott, Jour. Agr. Res., 26, 1923, 157; *Pseudomonas panici* Stapp, in Sorauer, Handb. d. Pflanzenkrank., 2, 5 Aufl., 1928, 27; *Phytomonas panici* Bergey et al., Manual, 3rd ed., 1930, 269) From M. L. *Panicum*, a generic name.

Rods: 0.69 by 1.66 microns. Capsules. Motile by 1 or rarely 2 polar flagella. Gram-negative.

Gelatin: Liquefaction slow.

Beef agar colonies: Round, white, smooth, glistening, margins at first entire, later undulate.

Broth: Moderate turbidity in 24 hours. Thin pellicle. Medium brownish.

Milk: Alkaline and clears.

Nitrites are produced from nitrates

Indole not produced.

Hydrogen sulfide produced.

No gas from carbohydrates.

Starch: Hydrolysis moderate

Optimum temperature 33°C. Maximum 45°C. Minimum 5°C

Optimum pH 6.15 to 6.3. pH range 5.4 to 10.0.

Aerobic

Distinctive characters: Differs from *Pseudomonas andropogoni* in that it liquefies gelatin, produces nitrites from nitrates, and does not infect sorghum and broom corn.

Source: Isolation from water soaked lesions on leaves, sheaths and culms of millet collected in Wisconsin and in S. Dakota

Habitat: Pathogenic on proso millet, *Panicum miliaceum*.

42. *Xanthomonas proteamaculans* (Paine and Stansfield) comb. nov. (*Pseudomonas proteamaculans* Paine and Stansfield, Ann. Appl. Biol., 6, 1919, 38; *Phytomonas proteamaculans* Bergey et al., Manual, 3rd ed., 1930, 247; *Bacterium proteamaculans* Elliott, Man. Bact. Plant Path., 1930, 186.) From M. L. *Protea*, a generic name; *maculans*, spotting.

Rods: 0.6 to 0.8 by 0.8 to 1.6 microns

Motile with 1 to 3 polar flagella. Gram-positive.

Gelatin: Liquefaction.

Agar slant: Growth wet-shining, dirty white with a faint yellow tinge.

Broth: Turbid in 24 hours. Slight ring.

Milk: Acid with soft curd after 2 days. Later a separation of whey.

Nitrites are produced from nitrates.

Acid and gas from glucose, sucrose and mannitol. No acid or gas from lactose.

Starch: Slight hydrolysis.

Source: Repeated isolation from a leaf-spot of *Protea* in England.

Habitat: Pathogenic on *Protea cynaroides*.

43. *Xanthomonas manihotis* (Arthaud-Berthet) *comb. nov.* (*Bacillus manihotis* Arthaud-Berthet by Bondar, Chacaras and Quintaes 5(4), 1912, 15; *Bacillus manihotis* Bondar (and Arthaud-Berthet), Bol. Agric., São Paulo, 16, 1915, 513; *Bacterium manihotis* Drummond and Hipolito, Ceres, 2, 1911, 298; *Phytomonas manihotis* Viegas, Rev. d. Agr., Pieraci-caba, 15, 1910, 475) From M. L. *Manihotis*, a generic name

Description from Burkholder, Phytopath., 32, 1912, 147

Rods: 0.35 to 0.93 by 1.4 to 2.8 microns. Gram-negative and mostly non-motile. One isolate showed a few cells with 1 polar flagellum. Amaral (Instit. Biol., São Paulo, Arq., 13, 1912, 120) states that the species is motile with one polar flagellum.

Gelatin: Liquefaction.

Beef-extract-peptone agar: Streaks raised, ivory-color, smooth, shiny, with edges entire.

Potato-glucose agar: Growth abundant, white to hyaline, very mucoid.

Broth: Turbid with a whitish granular ring.

Litmus milk: Litmus reduced and milk clears. With return of color, litmus is purple.

Indole not formed.

Hydrogen sulfide is formed

Nitrites produced from nitrates (Drummond and Hipolito, *loc. cit.*).

Asparagine not used as a nitrogen and carbon source. No growth in nitrate synthetic broth.

Weak growth but slight acid production in synthetic medium plus glucose, d-galactose, d-fructose, d-xylose, maltose and sucrose. No growth in rhamnose, l-arabinose, d-lactose, glycerol, mannitol and salicin. Good growth with alkaline reaction in same medium plus salts of the following acids: acetic, citric, malic, maleic and succinic. The salts of formic, hippuric, lactic and tartaric acids were not utilized.

Starch not hydrolyzed. Amaral (*loc. cit.*) finds hydrolysis.

Lipolytic action slight.

Aerobic.

Optimum temperature 30°C. Maximum 35°C. Minimum 5°C.

Source: First isolated from the cassava, *Manihotis utilissima* in Brazil.

Habitat: Produces a wilt disease on various species of *Manihotis*.

44. *Xanthomonas rubrisubalbicans* (Christopher and Edgerton) *comb. nov.* (*Phytomonas rubrisubalbicans* Christopher and Edgerton, Jour. Agr. Res., 41, 1930, 266; *Bacterium rubrisubalbicans* Burgwitz, Phytopathogenic Bacteria, Leningrad, 1935, 105.) From *L. ruber*, red; *subalbicans*, nearly white.

Rods: Short with polar flagella. Capsules. Gram-negative.

Gelatin: No liquefaction.

Bacto-glucose agar colonies: Circular, glistening, viscid, milky gray to buff. Margins translucent, entire.

Broth: Turbid after 24 hours. Pellicle and aropy sediment.

Indole produced.

Hydrogen sulfide produced.

No gas from carbohydrates.

Starch hydrolyzed.

Optimum temperature 30°C.

Optimum pH 6.8 to 8.0.

Source: Isolated many times from mottled stripe of sugar cane in Louisiana.

Habitat: Pathogenic on sugar cane, Johnson's grass and sorghum.

45. *Xanthomonas cannae* (Bryan) comb. nov. (*Bacterium cannae* Bryan, Jour. Agr. Res., 21, 1921, 152, *Phylomonas cannae* Bergey et al., Manual, 1st ed., 1923, 188; *Pseudomonas cannae* Stapp, in Sorauer, Handb. d. Pflanzenkrank., 2, 5 Aufl., 1928, 65) From *Cr. canna*, a reed; M. L. *Canna*, a generic name

Rods: 0.5 to 0.7 by 1.0 to 2.0 microns  
Motile with 1 to 3 polar flagella Cap-  
sules. Gram-negative

Gelatin: Slow liquefaction  
Agar streaks: Filiform, white, moist,  
with thin margins and granular centers  
Broth: Turbid, heavy sediment  
Milk: Alkaline and clears  
Nitrites are produced from nitrates  
Indole not produced  
Hydrogen sulfide produced  
Optimum temperature 35°C. Maxi-  
mum 40°C. Minimum 5°C  
Aerobic.

Source: Isolated from diseased canna leaves collected in Washington, D. C. and in Illinois.

Habitat: Causes disease in *Canna indica*.

46. *Xanthomonas zingiberi* (Uyeda) comb. nov. (Uyeda, Cent. f. Bakt., II Abt., 17, 1907, 383, *Pseudomonas zingiberi* Uyeda, Rept. Imp. Agr. Exp. Sta., Japan, No. 35, 1908, 114; *Bacterium zingiberi* Nakata, see Elliott, Man. Bact. Plant Path., 1930, 266, *Phylomonas zingiberi* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 437) From *L. zingiberis*, ginger; M. L. *Zingiber*, a generic name.

Description from Stapp, in Sorauer,

Handb. d. Pflanzenkrank., 2, 5 Aufl., 1928, 65.

Rods 0.5 to 1.1 by 0.75 to 1.8 microns.  
Non-motile at first, later a polar flagel-  
lum Gram-negative.

Gelatin: Liquefaction

Agar colonies: White.

Milk: Coagulation and peptonization of the casein.

Nitrites are produced from nitrates.

Indole not formed

Hydrogen sulfide is formed.

No gas from glucose

Optimum temperature 28°C. Maxi-  
mum 40°C. Minimum 5°C

Source: Isolated from ginger plant showing a rot at the base of the sprouts

Habitat: Pathogenic on ginger, *Zingiber officinale*.

47. *Xanthomonas conyae* (Uyeda) comb. nov. (*Pseudomonas conyae* Uyeda, Bot. Mag. Tokyo, 24, 1910, 182; *Bacterium conyae* Elliott, Man. Bact. Plant Path., 1930, 121, *Phylomonas conyae* Magrou, in Hauduroy et al., Dict. d. Bact. Path., Paris, 1937, 347.) From M. L. *conyae*, the specific name of the plant which this species attacks

Description from Elliott (loc. cit.).

Rods 0.75 to 1.0 by 1.5 microns.  
Motile with 1 to 4 polar flagella Gram-  
positive

Gelatin colonies: Circular to irregular,  
light yellow

Broth: Pellicle formed.

Milk: Coagulation

Conyae: Liquefied

Nitrites produced from nitrates

Indole produced.

Hydrogen sulfide produced

Gas from glucose

Favorable temperature 24°C.

Habitat: Pathogenic on *Amorphophallus konjac*.

Appendix I: \* The following organisms placed in the genus *Pseudomonas* apparently belong in *Xanthomonas*. Some may even be plant pathogens although they were

\* Prepared by Prof. Robert S. Breed, New York State Experiment Station, Geneva, New York, July, 1943.

isolated from water, soil and similar sources. Pigment is usually yellow and is not water-soluble.

*Key to yellow and other chromogenic species in genus Pseudomonas.*

1. Colonies yellow.
  - a. Gelatin liquefied.
    - b. Nitrites produced from nitrates.
      - c. Acid and gas produced from glucose.
        1. *Pseudomonas fermentans*.
      - cc. Acid but no gas from glucose.
        2. *Pseudomonas trifolii*.
        3. *Pseudomonas xanthae*.
      - ccc. Action on glucose not recorded.
        4. *Pseudomonas caudata*.
    - bb. Nitrites not produced from nitrates.
      - c. Litmus milk acid or ferment lactose.
        5. *Pseudomonas perlurida*.
        6. *Pseudomonas iridescentis*.
      - cc. Litmus milk not coagulated. Yellow sediment.
        7. *Pseudomonas turcosa*.
      - ccc. Litmus milk slimy, alkaline.
        8. *Pseudomonas ochracea*.
    - aa. No liquefaction of gelatin.
      - b. Nitrites produced from nitrates.
        - c. Litmus milk, slow coagulation.
          9. *Pseudomonas cerevisiae*.
        - cc. Litmus milk, acid but no digestion.
          10. *Pseudomonas arguta*.
        - ccc. No growth in litmus milk.
          11. *Pseudomonas subcreta*.
        - cccc. Action on litmus milk, not recorded.
          12. *Pseudomonas pictorum*.
      - bb. Nitrites not produced from nitrates.
        - c. Butter colored pellicle on litmus milk.
          13. *Pseudomonas lacunogenes*.
        - cc. No surface pellicle.
          14. *Pseudomonas segnis*.
  2. Colonies on gelatin blue center surrounded by yellow zone with peripheral green zone.
    - a. Gelatin liquefied.
      - b. Nitrites produced from nitrates.
        15. *Pseudomonas lemonnierii*.

1. *Pseudomonas fermentans* von Wolzogen Kuhr. (von Wolzogen Kuhr, Cent. f. Bakt., II Abt., 85, 1932, 228; *Flavobacterium fermentans* Bergey et al., Manual, 4th ed., 1934, 155) From Latin, *fermento*, to ferment.

Rods: 0.4 to 0.6 by 1.7 to 3.4 microns,

with rounded ends, occurring singly and in pairs. Motile, with a single or occasionally 2 or 3 polar flagella. Gram-negative.

Gelatin colonies: Circular, grayish, with rapid liquefaction.

Gelatin stab: Liquefaction crateriform.

Agar colonies: Circular, slightly convex, opaque, gray by reflected, and light-brown by transmitted light

Agar slant: Gray, becoming yellowish

Broth: Turbid with pellicle.

Litmus milk: Acid.

Potato: Gray to yellowish growth

Indole is formed

Nitrites produced from nitrates

Acid and visible gas from glucose, lactose and sucrose.

Acetylmethylcarbinol is formed

Ammonia is formed from peptone and asparagin.

Hydrogen sulfide is formed

Starch is hydrolyzed

Lipase is formed. Catalase positive

Aerobic, facultative

Optimum temperature 37°C.

Distinctive character Produces gas in lactose fermentation tubes

Source: Ten cultures from the larvae of a midge (*Chironomus plumosus*) and from filtered water.

Habitat: Unknown.

2. *Pseudomonas trifolii* Huss. (Huss, Cent. f. Bakt., II Abt., 19, 1907, 68; *Flavobacterium trifolii* Bergey et al., Manual, 1st ed., 1923, 111) From Latin, *tres* (tri-), three; *folium*, leaf, M. L. *Trifolium*, clover.

Possible synonym *Bacillus annulatus* Wright. (Wright, Memoirs Nat. Acad. Sci., 7, 1895, 443; *Pseudomonas annulata* Chester, Man. Determ. Bact., 1901, 315, Relationship to *Bacillus annulatus* Zimmermann uncertain. Die Bakt. unserer Trink- und Nutzwässer, Chemnitz, II Reihe, 1899, 30; *Flavobacterium annulatum* Bergey et al., Manual, 1st ed., 1923, 110.)

According to Mack (Cent. f. Bakt., II Abt., 85, 1936, 218) the following organism is to be regarded as identical with *Pseudomonas trifolii*: *Bacillus mesentericus aureus* Winkler (Cent. f. Bakt., II Abt., 5, 1899, 577) regarded by Burri (Cent. f. Bakt., II Abt., 10, 1902, 756) and Duggeli (Cent. f. Bakt., II Abt., 12, 1904, 602)

as identical with the organism which Duggeli (*loc. cit.*) names *Bacterium herbicola aureum*. The organism studied as *Bacterium herbicola* by Hüttig (Cent. f. Bakt., II Abt., 84, 1931, 231) is not regarded as identical with the Burri and Duggeli organism by Mack. Beijerinck (Cent. f. Bakt., II Abt., 15, 1905, 266) states that *Bacillus herbicola* of Burri and Duggeli is identical with his *Bacillus angulomerans* (Botan. Ztg., 1888, 749) If so, this binomial has priority.

Rods. 0.5 to 0.7 by 0.75 to 2.0 microns, occurring singly, in pairs and in chains. Motile, possessing a single polar flagellum. Gram-negative.

Gelatin colonies: Convex, smooth, moist, glistening, grayish-yellow.

Gelatin stab: Napiform liquefaction

Agar colonies: Small, circular, grayish, becoming brownish-yellow

Agar slant: Yellowish, becoming brownish-yellow streak, lacerate margin.

Broth: Turbid, with grayish-yellow pellicle and sediment.

Litmus milk: Slowly coagulated; alkaline; with yellow ring.

Potato: Thick, yellowish, flat, smooth, glistening

Hydrogen sulfide produced

Indole is formed

Acid from glucose, sucrose, xylose, arabinose, and mannitol. No acid from lactose.

Nitrites produced from nitrates.

Cultures have an agreeable odor.

Volutin formed.

Aerobic, facultative.

Optimum temperature 33° to 35°C.

Source: Isolated from clover hay.

Habitat: Evidently a common organism on the leaves of plants.

3. *Pseudomonas xanthae* Zettnow. (Zettnow, Cent. f. Bakt., I Abt., Orig., 77, 1915, 220; *Flavobacterium zettnowii* Bergey et al., Manual, 1st ed., 1923, 112, *Flavobacterium xanthum* (sic) Bergey et al., Manual, 3rd ed., 1930, 145.) From *Gr. xanthus*, yellow.

Rods: 0.5 to 0.6 by 0.4 to 1.4 microns. Motile, possessing a single or occasionally two or more very long (20 microns) polar flagella. Gram-negative.

Gelatin colonies: Circular, yellow, granular.

Gelatin stab: Pale-yellow surface growth. Brownish yellow under surface colonies. Saccate liquefaction.

Agar slant: Dark yellow, glistening, with dark yellow sediment in water of condensation. Pigment not water-soluble.

Broth: Turbid.

Litmus milk: Slightly acid. Litmus reduced.

Potato: Grayish yellow to brownish growth.

Indole formed.

Nitrites are produced from nitrates.

Acid formed in glucose.

Starch hydrolyzed.

Blood serum not liquefied.

Aerobic, facultative

Optimum temperature 30°C.

Source: Air contamination.

4. *Pseudomonas caudata* (Wright) Conn. (*Bacillus caudatus* Wright, Memoirs Nat. Acad. Sci., 7, 1895, 444; *Bacterium caudatus* Chester, Annual Rept. Del. Col. Agr. Exp. Sta., 9, 1897, 107, Conn. Jour. Agr. Res., 16, 1919, 313; *Flavobacterium caudatum* Bergey et al., Manual, 1st ed., 1923, 109) From Latin, *cauda*, tail

Rods: Long, granular, slender, occurring singly, in pairs and in chains. Appear like cocci in old cultures. Motile, possessing a polar flagellum (Conn). Gram-negative.

Gelatin colonies: Yellow, translucent, smooth, undulate.

Gelatin stab: Villous growth in stab. Crateriform liquefaction

Agar slant: Yellow to orange, glistening, translucent, slightly spreading. May lose power to form pigment.

Broth: Turbid, with yellow sediment.

Litmus milk: Unchanged.

Potato: Dark yellow, raised, rough, spreading.

Indole not formed.

Nitrites and ammonia produced from nitrates.

Ammonia produced from peptone.

Starch is digested.

Aerobic, facultative.

Optimum temperature 25°C.

Habitat: Water.

5. *Pseudomonas perflurida* Kellerman et al. (Kellerman, McBeth, Scales and Smith, Cent. f. Bakt., II Abt., 59, 1913, 516; also McBeth, Soil Sci., 1, 1916, 472; *Cellulomonas perlurida* Bergey et al., Manual, 1st ed., 1923, 163.)

Rods: 0.4 by 1.0 micron. Motile with one to three polar flagella. Gram-negative.

Gelatin stab: Liquefaction.

Agar slant: Moderate, flat, faint yellow growth.

Broth: Turbid in 5 days.

Litmus milk: Acid. Peptonization after 16 days.

Potato: Scant yellow growth with bleaching along line of growth.

Indole not formed.

Nitrites not produced from nitrates.

Ammonia is produced.

Acid from glucose, maltose, lactose, sucrose, starch, glycerol and mannitol.

Aerobic, facultative.

Optimum temperature 20°C.

Source: Soil from Virginia, Louisiana and Missouri.

Habitat: Soil.

5a. *Pseudomonas perlurida* var. *virginiana* Kellerman et al. (loc. cit.). Does not grow on potato and liquefies gelatin rapidly.

Source: Soil from Virginia.

6. *Pseudomonas iridescent* Stanier. (Jour. Bact., 43, 1911, 512.) From Latin, *iridescent*.

Rods: 0.2 to 0.3 by 1.5 to 7.0 microns, average length 5.0 to 6.0 microns, occurring singly. Non-motile. Gram-negative.

Sea water gelatin stab: Filiform growth. Liquefaction by some strains.

Sea water agar colonies: Concave, 2 to 3 mm in diameter, smooth, glistening, translucent, pale yellow, edge irregular. After 2 to 3 days a marked iridescence. Later colonies rough, opaque, bright yellow, sunken central portion with translucent periphery.

... spreading, pale yellow, iridescent, but...

Sea water broth: Turbid, light yellow, granular pellicle.

Indole not formed.

Nitrites not produced from nitrates

Hydrogen sulfide not produced

Catalase positive.

Urease negative.

Acid from xylose, glucose, galactose, lactose, maltose, sucrose and cellobiose. No acid from arabinose. Starch and cellulose are attacked

Aerobic.

Optimum temperature 23°C. Minimum 5°C. Maximum 30°C.

Salt range: 0.25 to 6.0 per cent. Optimum 1.0 to 4.0 per cent.

Source: Sea water

Habitat: Common along the coast of the North Pacific.

**7. *Pseudomonas turcosa* (Zimmermann) Migula.** (*Bacillus turcosa* Zimmermann, Bakt. unserer Trink- und Nutzwässer, Chemnitz, 2, 1891, 32; Migula, Syst. d. Bakt. 2, 1900, 937; *Flavobacterium turcosum* Bergey et al., Manual, 1st ed., 1923, 111) From M. L. turcosa, turquoise

Rods: 0.5 by 1.05 to 1.82 microns, occurring singly. A short polar flagellum (Migula). Gram-negative

Gelatin colonies: Small, translucent, yellow.

Gelatin stab: Small, yellow, convex surface growth, with slight brownish flat. Liquefaction, with grayish to greenish color in liquefied portion

Agar slant: Abundant, clustering, greenish to sulfur yellow streak.

Broth: Slightly turbid with yellow sediment.

Litmus milk: No coagulation. Yellow sediment.

Potato: Clear chromium yellow growth over entire surface.

Indole is not formed.

Nitrites not produced from nitrates.

Acid from glucose. Slight action on sucrose

Aerobic, facultative.

Optimum temperature 30°C.

Source: Isolated by Tataroff from a well in Dorpat (Die Dorpaten Wasserbakterien, Inaug. Diss., 1891, 52, No. 21).

Habitat: Water, sea water.

**8 *Pseudomonas ochracea* (Zimmermann) Chester.** (*Bacillus ochraceus* Zimmermann, Bakt. unserer Trink- und Nutzwässer, Chemnitz, 2, 1890, 60; Chester, Determinative Bacteriology, 1901, 316; *Flavobacterium ochraceum* Bergey et al., Manual, 1st ed., 1923, 110; *Chromobacterium ochraceum* Topley and Wilson, Princ. Bact. and Immun., 1, 1931, 405) From Greek, *ochros*, pale yellow.

Rods: 0.7 to 0.8 by 1.2 to 4.5 microns, occurring in pairs and longer chains. Slow undulatory motion (Zimmermann). Polar flagella (Lehmann and Neumann, Bakt. Diag., 1 Aufl., 2, 1896, 235) Gram-negative

Gelatin colonies: Pale yellow to golden, ochre yellow, slightly raised, with slightly fringed margin, granular

Gelatin stab: Yellowish to yellow-gray surface growth. Infundibuliform liquefaction. Pale yellow to ochre yellow sediment

Agar colonies: Thin, flat, yellowish, smooth

Agar slant: Thin, yellowish-gray to ochraceous growth

Broth: Slightly turbid, with pale yellow sediment

Litmus milk: Medium becomes slimy; alkaline.

Potato: Ochre yellow streak

Indole is formed.

Nitrites not produced from nitrates.  
 Hydrogen sulfide is formed.  
 Aerobic, facultative.  
 Optimum temperature 35°C.  
 Source: Chemnitz tap water.  
 Habitat: Water.

9. *Pseudomonas cerevisiae* Fuhrmann. (Fuhrmann, Cent. f. Bakt., II Abt., 16, 1906, 309; *Flavobacterium cerevisiae* Bergey et al., Manual, 1st ed., 1923, 111.) From Latin, *cerevisia*, beer.

Rods: Straight and slightly curved, 0.6 by 1.5 to 2.0 microns, occurring singly and in chains. Motile, possessing tuft, four to six polar flagella. Gram-negative.

Gelatin colonies: Circular, white, slightly contoured, becoming brownish-yellow.

Gelatin stab: Slight yellowish growth in stab. No liquefaction.

Agar colonies: Thin, spreading, contoured.

Agar slant: Moist, glistening, thin, pale yellow, spreading, contoured.

Litmus milk: Slow coagulation.

Potato: Yellowish-brown, spreading growth.

Indole not formed.

Nitrites produced from nitrates.

No gas from glucose.

Aerobic, facultative.

Optimum temperature 30°C

Source: Isolated from beer.

Habitat: Unknown.

10. *Pseudomonas arguta* McBeth. (McBeth, Soil Science, 1, 1916, 465; *Cellulomonas arguata* (sic) Bergey et al., Manual, 1st ed., 1923, 164.) From Latin, *arguo*, to show.

Rods: 0.3 by 0.8 micron. Motile with one or two polar flagella. Gram-negative.

Gelatin stab: Moderate, yellowish growth. No liquefaction in 30 days.

Agar colonies: Circular, slightly convex, soft, grayish-white, granular, entire.

Agar slant: Scant, grayish-white growth.

Potato agar slant: Moderate, yellowish, glistening.

Broth: Turbid.

Ammonia cellulose agar: Enzymatic zone 2 to 3 mm in 30 days.

Filter paper broth: Paper is reduced to loose flocculent mass which disintegrates very readily on slight agitation. More rapid decomposition when the broth contains ammonium sulfate, potassium nitrate, peptone or casein as sources of nitrogen.

Litmus milk: Acid, not digested.

Potato: No growth.

Indole not formed.

Nitrites produced from nitrates.

Ammonia not produced.

Acid from glucose, maltose, lactose, starch. No acid from glycerol, mannitol or sucrose.

Aerobic, facultative.

Optimum temperature 20°C.

Source: Isolated twice from California soils.

Habitat: Soil.

11. *Pseudomonas subcreta* McBeth and Scales. (McBeth and Scales, Bur. Plant Industry, U. S. Dept. Agr., Bul. 266, 1913, 37; *Cellulomonas subcreta* Bergey et al., Manual, 1st ed., 1923, 164.) From Latin, *sub*, under, imperfect; *creta* chalk.

Rods: 0.3 by 1.4 microns. Motile with one to five polar flagella. Gram-negative.

Gelatin stab: Filiform growth, no liquefaction.

Cellulose agar: No surface growth. Moderate, generally faint yellow growth in medium, area of growth sunken.

Agar slant: Glistening, smooth, moist, vitreous to faint yellow.

Starch agar: Enzymatic zone 2 to 4 mm.

Broth: No growth.

Litmus milk: No growth.

Potato: Growth scanty, concave due to slight liquefaction, white to faint yellow. Bleached around growth.

Indole not formed.

Trace of nitrites produced from nitrates.

Ammonia not produced.

Acid from glucose, lactose, maltose,

sucrose and starch. No acid from glycerol or mannitol

Aerobic, facultative

Optimum temperature 20°C

Habitat: Soil.

12. *Pseudomonas pictorum* Gray and Thornton. (Gray and Thornton, Cent. f. Bakt., II Abt., 73, 1928, 89, *Achromobacter pictorum* Bergey et al., Manual, 3rd ed., 1930, 217) From Latin, *picti*, the Picts of Eastern Scotland.

Rods: 0.5 to 0.8 by 1.5 to 5.0 microns. Motile usually with a single polar flagellum. Gram-negative

Gelatin colonies Circular, greenish-yellow, convex, smooth, glistening, entire.

Gelatin stab: No liquefaction

Agar colonies: Circular, yellow, convex, smooth, glistening, entire

Agar slant: Filiform, yellow, convex, smooth, glistening, entire

Broth: Turbid.

Nitrites produced from nitrates

Starch not hydrolyzed

Acid from glucose and maltose

Attacks phenol.

Aerobic, facultative.

Optimum temperature 25°C

Source: One culture from soil

Habitat: Soil

13. *Pseudomonas lacunogenes* Goresline. (Jour. Bact., 26, 1933, 447) From Latin *lacuna*, dimple and *genero*, to produce.

Short rods. 0.2 to 0.3 by 1.0 to 1.2 microns, with pointed ends, occurring singly or in pairs. Motile with a single polar flagellum from 2 to 15 microns in length. Gram-negative

Plain gelatin stab: No growth

Nutrient gelatin stab: Growth brownish-yellow, half-way down stab, heavier at surface. No liquefaction

Nutrient agar colonies: Small, yellow, surface of the agar pitted or dimpled. After 5 days colonies 5 to 7 mm in diam-

eter, orange-yellow, slightly raised, surrounded by a depression.

Nutrient agar slant: Growth heavy, light orange-yellow, consistency of warm butter, edge entire, slightly raised. Shallow depression formed on each side of streak. Agar softened beneath growth.

Nutrient broth: Turbid in 48 hours. Light orange-yellow pellicle; considerable viscous sediment.

Litmus milk: Alkaline; butter-colored pellicle. Reduction in bottom of tube after 10 days. No curd. No digestion.

Potato: Growth moderate, orange-yellow, smooth. No darkening

Indole not formed.

Nitrites not produced from nitrates.

Starch agar plates not hydrolyzed.

Utilizes arabinose, galactose, lactose, fructose, maltose, melzitose, raffinose, starch, xylose, glucose, mannose, sucrose, pectin, rhamnose, salicin and dextrin. No growth in dulcitol, erythritol, glycerol, sorbitol, mannitol or inulin.

Limits of pH: 5.4 to 10.0

Temperature relations: Optimum 28°C. Good growth at 25°C. Moderate growth at 20° and at 37°C. No growth at 10° and at 42°C

Facultative anaerobe.

Distinctive characters. Softens agar; considerable change in viscosity of agar due to this digestion; utilization of ammonium sulfate as nitrogen source

Source: Three cultures isolated from an experimental trickling filter receiving creamery wastes.

Habitat: Probably widely distributed in nature.

14. *Pseudomonas segnis* Goresline (Jour. Bact., 26, 1933, 452) From Latin *segnis*, non-energetic

Short rods: 0.2 to 0.3 by 1.0 to 1.2 microns, with pointed ends, occurring singly or in pairs. Motile with a single polar flagellum. Gram-negative

Plain gelatin stab: No growth.

Nutrient gelatin stab: Growth yellow, half-way down stab, best at surface. No liquefaction.

Nutrient agar colonies: Very small, light yellow; surface pitted. After 5 days colonies 5 mm in diameter.

Nutrient agar slant: Growth heavy, orange-yellow, consistency of warm butter; edge entire, slightly raised; slight depression formed on each side of growth. Agar softened beneath growth.

Nutrient broth: Turbid in 48 hours. No pellicle or surface growth. Moderate amount of sediment. Old cultures with a yellow ring at surface and occasionally a loose membrane.

Litmus milk: Slightly alkaline after 10 days. No reduction. No surface growth.

Potato: Scant yellow-orange growth. No darkening.

Indole not formed.

Nitrites not produced from nitrates.

No  $H_2S$  produced.

Starch not hydrolyzed.

Utilizes arabinose, glucose, galactose, lactose, fructose, maltose, mannose, xylose, sucrose, melzitose and raffinose.

Limits of pH: 5.8 to 9.0.

Temperature relations: Optimum 28°C. Good growth at 25°C. Moderate growth at 20° and at 37°C. No growth at 10° and at 42°C.

Facultative anaerobe.

Distinctive characters: Softens agar; considerable change in viscosity of agar due to this digestion.

Source: Isolated from an experimental trickling filter receiving creamery wastes.

Habitat: Probably widely distributed in nature.

15. *Pseudomonas lemonnierii* (Lasseur) *comb nov* (*Bacillus lemonnierii* Lasseur, Compt. rend Soc Biol. Paris, 74, 1913, 47; Bul. de la Soc. des Sci. de Nancy, 1924; *Flavobacterium lasseuri* Bergey et al., Manual, 3rd ed., 1930, 144.) Named for Prof. G. le Monnier, a French scientist.

Rods 0.5 to 0.7 by 1.0 to 2.0 microns, occurring singly and in pairs. Motile

with a single polar flagellum. Gram-negative.

Gelatin colonies (glucose): Circular with blue center, a granular, yellow zone and a peripheral blue zone. Rapid liquefaction with blue crystals.

Gelatin stab: Liquefied.

Agar colonies: Circular, yellowish, lobate margin.

Agar slant: Yellowish streak, smooth, glistening.

Broth: Turbid with thin pellicle.

Litmus milk: After 48 hours the surface of the milk becomes yellow to cream color turning blue. A soft coagulum is formed.

Potato: Raised growth, Prussian blue in color, with variations.

Indole is not formed

Nitrites produced from nitrates.

Aerobic, facultative.

Optimum temperature 22° to 25°C.

Habitat: Water.

Appendix II:\* The following inadequately described species may belong to the genus *Xanthomonas*.

*Bacterium citri deliciosae* Passalacqua. (Rev. Pat. Veg., 24, 1934, 27.) Isolated from *Citrus* sp.

*Bacterium malvacearum* var. *barbadense* Evelyn. (Ann. Rept. Agric. Barbados for 1926-27, 1928, 15.) Isolated from cotton.

*Pseudomonas amaranti* (sic) Smith. (U. S. Dept. Agr., Div. Veg. Phys. and Path. Bull., 28, 1901, 153; *Bacterium amaranthi* Smith, Bact. in Relation to Plant Dis., 3, 1914, 148; *Phytomonas amaranthi* Bergey et al., Manual, 1st ed., 1923, 186.) Isolated from diseased amaranthus. Growth in culture similar to *Xanthomonas campestris* and *Xanthomonas hyacinthi*.

*Pseudomonas alutacea* Migula. (Ledergelber *Bacillus*, Tataroff, Die Dorpater Wasserbakterien, Inaug. Diss., Dorpat,

\* Prepared by Prof. Robert S. Breed, New York State Experiment Station, Geneva, New York, July, 1943.

1891, 61; Migula, Syst. d. Bakt., 2, 1900, 936 ) Isolated from water.

*Pseudomonas graveolans* Migula (*Bacillus aquatilis graveolens* Tataroff, Die Dorpater Wasserbakterien, Inaug. Diss., Dorpat, 1891, 48; Migula, Syst. d. Bakt., 2, 1900, 931.) Isolated from water  
Not *Pseudomonas graveolens* Levine and Anderson (Jour. Bact., 23, 1932, 343) isolated from musty eggs, and by Olsen

and Hammer (Iowa State Coll. Jour. Sci., 9, 1931, 125) from milk.

*Pseudomonas resinacea* Migula (Harzfarbener *Bacillus*, Tataroff, Die Dorpater Wasserbakterien, Inaug. Diss., Dorpat, 1891, 64; Migula, Syst. d. Bakt., 2, 1900, 935 ) Isolated from water.

*Xanthomonas taraxaci* Niederhauser (Phytopath., 33, 1943, 961.) Pathogenic on Russian dandelion (*Taraxacum kok-saghyz*)

### Genus III. *Methanomonas* Orla-Jensen \*

(Cent. f. Bakt., II Abt., 22, 1909, 311.)

Cells monotrichous, capable of obtaining energy from oxidation of methane to CO<sub>2</sub> and water.

The type species is *Methanomonas methanica* (Söhngen) Orla-Jensen.

1. *Methanomonas methanica* (Söhngen) Orla-Jensen. (*Bacillus methanicus* Söhngen, Cent. f. Bakt., II Abt., 16, 1906, 513; Orla-Jensen, Cent. f. Bakt., II Abt., 22, 1909, 311 ) From methane

Short rods: 0.5 to 0.8 by 2.0 to 3.0 microns, motile in young cultures by means of a single flagellum. In older cultures nearly spherical. Can be cultivated in an atmosphere composed of one part CH<sub>4</sub> and two parts air on washed agar containing the necessary inorganic salts. The growth is membranous

At the end of two weeks, the organisms changed an atmosphere containing 225 ml. CH<sub>4</sub> and 321 ml. O<sub>2</sub> to the following

CH <sub>4</sub>	0 ml.
CO <sub>2</sub>	78 ml.
O <sub>2</sub>	172 ml.

In addition, 21 ml. CO<sub>2</sub> was dissolved in the liquid.

Habitat: Presumably widely distributed in soil.

### Genus IV. *Acetobacter* Beijerinck †

(Proc. Kon. Akad. v. Wetenschap., Amsterdam, 2, 1900, 495.)

*Acetobacter aceti* first appeared (Kral's Sammlung v. Mikroorg., Prague, 1898, 4) as a synonym of *Bacterium aceti* Hansen. Beijerinck (loc. cit.) mentions *Acetobacter aceti* in a footnote of a later paper. The genus name *Acetobacter* was accepted by Fuhrmann (Beih. Bot. Centralbl., Orig., 19, 1903, 8) and others. From Latin, *acetum*, vinegar, *bacterium*, rod

Synonyms: ? *Ulna* Kützing, *Algae aquae dulcis*, etc., 11th decade, 1837; *Mycoderma* Thompson, Ann. d. Chem. u. Pharmacie, 83, 1852, 89; ? *Umbina* Nageli, Bericht über die Verhandlungen der bot. Section der 33. Versammlung deutscher Naturforscher und Ärzte, Bot. Ztg., 1857, 760; *Bacterium* Lanzi, N. Giorn. bot. ital., 1876, 257; *Torula* Saccardo, Atti Soc. Ven. Trent., 5, 1878, 315; *Bacteriopsis* (in part) Trevisan, Atti Accad. Fisico-Matematica Statistica Milano, Ser. 4, 3, 1885, 103; *Micrococcus* Maggi, Jour. Microg., 10, 1886, 161; *Bacillus* Schroeter, Kryptogamen Flora von Schlesien, 3, 1, 1886, 161; *Thermobacterium* Zeidler, Cent. f. Bakt., II Abt., 2, 1906, 733; *Acetobacter*

\* Prepared by Prof. D. H. Bergey, Philadelphia, Pennsylvania, December, 1922.

† Revised by Dr. C. D. Kelly, McGill Univ., Montreal, P. Q., Canada, July, 1933; further revision by Dr. Reese H. Vaughn, Univ. of California, Berkeley, California June, 1913.

*terium* Ludwig, in abstract of Hoyer's Inaug. Diss., Cent. f. Bakt., II Abt., 4, 1898, 867; *Acetimonas* Orla-Jensen, Cent. f. Bakt., II Abt., 22, 1909, 312.

In addition, the sub-generic names *Euacetobacter* and *Acetogluconobacter* have been proposed by Asai, Jour. Agr. Soc. Japan, 11, 1935, 502. The genus *Gluconobacter* and the sub-genera *Eugluconobacter* and *Gluconoacetobacter* Asai (*loc. cit.*) may be synonyms in whole or in part.

Individual cells ellipsoidal to long and rod-shaped, occurring singly, in pairs, or in short or long chains. Motile with polar flagella, or non-motile. Involution forms may be spherical, elongated, filamentous, club-shaped, swollen, curved or even branched. Young cells Gram-negative; old cells often Gram-variable. Obligate aerobes; as a rule strongly catalase positive, sometimes weakly so. Oxidize various organic compounds to organic acids and other oxidation products which may undergo further oxidation. Common oxidation products include acetic acid from ethyl alcohol, gluconic and sometimes ketogluconic acid from glucose, dihydroxyacetone from glycerol, sorbose from sorbitol, etc. Nutritional requirements vary from simple to complex. Development generally best in yeast infusion or yeast autolysate media with added ethyl alcohol or other oxidizable substrate. Optimum temperature variable with the species. Widely distributed in nature where they are particularly abundant in plant materials undergoing alcoholic fermentation; of importance to man for their role in the completion of the carbon cycle and for the production of vinegar.

The type species is *Acetobacter aceti* (Kützinger) Beijerinck.

*Key to species of genus Acetobacter.*

I. Oxidize acetic acid to carbon dioxide and water.

A. Capable of utilizing ammonium salts as a sole source of nitrogen (Hoyer's solution) \*

1. *Acetobacter aceti*.

B. Do not utilize ammonium salts as a sole source of nitrogen.\*

1. Forms a thick, zoogloeal, cellulose membrane on the surface of liquid media

2. *Acetobacter xylinum*.

2. Do not form a thick, zoogloeal membrane on the surface of liquid media.

3. *Acetobacter rancens*.

3a. *Acetobacter pasteurianum*.

3b. *Acetobacter kuetzingianum*.

II. Do not oxidize acetic acid.

A. Form pigments in glucose media.

1. Dark brown to blackish pigment.

4. *Acetobacter melanogenum*.

2. Pink to rose pigment.

5. *Acetobacter roseum*.

B. Do not form pigments.

1. Optimum temperature 30° to 35°C.

6. *Acetobacter suboxydans*.

2. Optimum temperature 20° to 25°C.

7. *Acetobacter oxydans*.

---

\* It is not known with certainty whether *Acetobacter pasteurianum* and *Acetobacter kuetzingianum* are capable of using inorganic nitrogen as a sole source of nitrogen for growth. However, since these two species are among those first described it is advisable to retain them for the present. See *Acetobacter rancens* Beijerinck.

1. *Acetobacter aceti* (Kützing) Beijerinck. (*Ulrina aceti* Kützing, *Algæ aquæ dulcis* etc., 11th derade, 1837, *Mycoderma aceti* Thompson, Ann d. Chem. u. Pharmacie, 83, 1852, 89, *Umbina aceti* Naegeli, Bericht über die Verhandlungen der bot. Section der 33. Versammlung deutscher Naturforscher und Ärzte, Bot. Ztg., 1857, 760, *Bacterium aceti* Lanzi, N. Giorn. bot. ital. 1876, 257; *Torula aceti* Saccardo, Atti Soc. Ven. Trent., 5, 1878, 315, *Bacteriopsis aceti* Trevisan, Atti della Accademia Lino-Medico-Statistica in Milano, Ser. 1, 3, 1885, 103; *Micrococcus aceti* Maggi, Jour. Microg., 10, 1886, *Bacillus aceti* Schmeier, Kryptogamen Flora von Schlesien, 3, 1, 1886, 161, *Bacillus aceticus* Flügge, Die Mikroorganismen, 1886, 311, Beijerinck, Kral's Sammlung v. Mikroorg., Prague, 1898, 7, Beijerinck, Proc. Kon. Akad. v. Wetensch., Amsterdam 2, 1900, 497; *Bacterium Hansenianum* Chester, Man. Determin. Bact., 1901, 126. From Latin *acetus*, vinegar.

Roze: 0.4 to 0.5 by 1.0 to 2.0 microns, occurring singly and in long chains, frequently showing large club-shaped forms. Stain yellow with iodine solution. Motility variable. Motile cells possess a single polar flagellum (Vaughn, Jour. Bact., 46, 1917, 394). Forms large, slimy colonies on beer gelatin containing 10 per cent sucrose.

Forms slimy pellicle on fluid media or ring or turbidity with out pellicle.

Acid from glucose, ethyl alcohol, propyl alcohol and glycol. No acid from arabinose, fructose, galactose, meliose, sucrose, maltose, lactose, raffinose, dextrin, starch, glycogen, inulin, methyl alcohol, isopropyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol, glycerol, erythritol, mannitol, dulcitol and inositol alcohols (Hesseltine, Die Gärung, Leipzig, 2, 1908, 167).

Acid from

Differentiative characters: Marked by its liquefying power on gelatin and complete oxidation of carbohydrate glucose, methyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol, glycerol, erythritol, mannitol, dulcitol and inositol alcohols.

gen salts as a sole source of nitrogen (Hoyer, Inaug. Diss., Leiden, 1898, 43; Beijerinck, Cent. f. Bakt., II Abt., 4, 1898, 215); growth and oxidative activity in association with fermenting yeasts (Vaughn, Jour. Bact., 36, 1938, 360).

Optimum temperature 30°C. Growth occurs between 10° and 42°C.

Habitat: Vinegar; souring fruits, vegetables and beverages.

2. *Acetobacter xylinum* (Brown) Holland. (*Bacterium xylinum* Brown, Jour. Chem. Soc., London, 49, 1886, 439; Holland, Jour. Bact., 5, 1920, 216; *Bacillus xylinus* Holland, *ibid.*, 221). From *Gr. xylinus*, wooden (in reference to the cellulose in the membrane).

Roze, about 2 microns long, occurring singly and in chains. The cells have a slimy envelope which gives the cellulose reaction.

A film forms on the surface of liquids. This film becomes cartilaginous and falls to the bottom. This mucous film forms on all liquid media in which growth occurs, the nature of the medium influences the thickness of the film which may vary from 1 to 2.0 millimeters.

X-ray pattern studies made by Khonovine, Champetier and Sutra (Compt. rend. Acad. Sci. Paris, 194, 1912, 318) and by Bartha and Hildert (Can. Jour. Research, 19, 1931, 170) have shown that the cellulose contained in the membrane formed by *Acetobacter xylinum* is identical with cotton cellulose.

Acid from glucose, ethyl alcohol, propyl alcohol and glycol. No acid from arabinose, fructose, galactose, meliose, sucrose, maltose, lactose, raffinose, dextrin, starch, methyl alcohol, isopropyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol, glycerol, erythritol, mannitol, dulcitol and inositol alcohols (Hesseltine, Die Gärung, Leipzig, 2, 1908, 167).

Acid from

Differentiative characters: The production of thin, leather-like, mucous cell wall membrane, the cellulose cell wall.

Optimum temperature 20°C.

Habitat: Vinegar; souring fruits, vegetables and beverages.

3. *Acetobacter rancens* Beijerinck. (*Bacterium rancens* Beijerinck, Cent. f. Bakt., II Abt., 4, 1898, 211; Beijerinck, Kral's Sammlung v. Microorg., Prague, 1898, 4.) From *L. rancens*, being rancid

Beijerinck (*loc. cit.*) in a footnote stated that "two of the many varieties of *B. rancens* have been described by Henneberg under the names of *B. oxydans* and *B. acetosum*. Hansen erroneously called this species *B. acetii* as did Brown. Neither Hansen nor Brown knew *B. acetii* Pasteur." No further morphological description is given.

The following description is taken in part from a study of a culture of *Acetobacter rancens* received from Kluyver (Vaughn).

Rods with the usual morphological appearance of cultures of acetic acid bacteria. Gram negative. Motility variable. Motile cells possess a single polar flagellum (Vaughn, Jour. Bact., 46, 1943, 394). Involution forms commonly appear as filaments and enlarged cells.

Wort agar slant: Growth abundant, butyrous, pale-buff in color in one week.

Yeast infusion, glucose, calcium carbonate slant: Growth abundant, butyrous and cream-colored in one week.

With petri dish cultures well isolated colonies are large, smooth and butyrous on either medium.

Broth cultures containing peptone or yeast infusion form a mucilaginous, slimy pellicle. Beijerinck (*loc. cit.*) called this polysaccharide pellicle, cellulose-like and intimated that the mucilaginous material in the pellicle was somewhat different from that produced by *Acetobacter xylinum*. The pellicle material stained blue when treated with iodine and hydroiodic acid.

Acid from glucose, ethyl alcohol, propyl alcohol, butyl alcohol, glycol, adonitol, mannitol and sorbitol. No acid from numerous other compounds tested.

Distinctive character: Production of a thin, mucilaginous, slimy, polysaccharide membrane on the surface of liquids as compared with the thick, true cellulose membrane of *Acetobacter xylinum* grown under the same conditions. Beijerinck (*loc. cit.*) reported the production of a cellulose-like membrane with some cultures of *Acetobacter rancens*.

Source: Isolated from shavings in the quick vinegar process.

Habitat: Found in fermented grain mash, malt beverages, mother of vinegar.

Beijerinck (Cent. f. Bakt., II Abt., 4, 1898, 211) thought that the next two species were hardly more than varieties of *Acetobacter rancens*.

3a. *Acetobacter pasteurianum* (Hansen) Beijerinck. (*Mycoderma pasteurianum* Hansen, Compt. rend. d. Trav. d. Lab. d. Carlsberg, 1, 1879, 96; *Bacterium pasteurianum* Zopf, Die Spaltpilze, 2 Aufl., 1884, 49; Beijerinck, Kral's Sammlung v. Microorg., Prague, 1898, 7.) Named for Pasteur, the French chemist and bacteriologist.

Rods: 0.4 to 0.8 by 1.0 micron, occurring singly and in chains, at times showing thick, club-shaped forms. Motility variable. Motile cells possess a single polar flagellum (Vaughn, Jour. Bact., 46, 1943, 394). Stains blue with iodine.

Wort gelatin colonies: Small, circular, entire, gray, slimy.

Forms a dry, wrinkled folded pellicle on double beer with one per cent alcohol.

Meat infusion gelatin: Widespread, later rosette form, toothed.

Acid from glucose, ethyl alcohol, propyl alcohol and glycol. No acid from arabinose, fructose, galactose, sorbose, sucrose, maltose, lactose, raffinose, dextrin, starch, glycogen, inulin, methyl alcohol, isopropyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol, glycerol, erythritol, mannitol, dulcitol and acetaldehyde (Henneberg, Die deutsch. Essig-ind., 2, 1898, 147).

Aerobic.

Optimum temperature 30°C. Growth occurs between 5° and 42°C.

Habitat: Vinegar; beer and beer wort

3b. *Acetobacter kuetzingianum* (Hansen) Bergey et al (*Bacterium kuetzingianum* Hansen, Compt. rend. d. Trav. d. Lab. d. Carlsberg, 3, 1894, 191; Bergey et al., Manual, 1st ed., 1923, 35) Named for Kuetzing, the German botanist

Short, thick rods, occurring singly. Rarely forming chains of notable length. Capsule stained blue with iodine and with potassium iodide. Non-motile

Double beer gelatin colonies: Small, entire, with vermiform surface

Wort gelatin colonies: Small, entire, with surface free of wrinkles

Double beer: Forms a rather thick, folded pellicle. Distinguished from *Acetobacter aceti* in showing heavier growth above the surface of the media

Acid from glucose, ethyl alcohol, propyl alcohol and glycol. No acid from arabinose, fructose, galactose, sorbose, sucrose, maltose, lactose, raffinose, dextrin, starch, glycogen, inulin, methyl alcohol, isopropyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol, glycerol, erythritol, mannitol, dulcitol and acetaldehyde (Henneberg, Die deutsch. Essig-ind., 2, 1893, 147).

Aerobic.

Optimum temperature 31°C, maximum 42°C, minimum 6 to 7°C

Habitat: Beer. Found in double beer

4. *Acetobacter melanogenum* Beijerinck. (Cent. f. Bakt., II Abt., 29, 1911, 175) From Greek *melas* (melan), black; *-genes*, producing.

Rods. Non-motile or motile. Motile cells possess a single polar flagellum (Vaughn, Jour. Bact., 46, 1943, 394)

Gelatin: Apparent liquefaction probably caused by acid, not an enzyme. When held on artificial media for some time, the power of liquefying gelatin is lost, probably due to a slower production of acid. Deep brown pigment produced;

gelatin becomes insoluble in boiling water and in trypsin solution.

Beer- or wort-gelatin plates: Characteristic dark brown, wide-spreading, diffuse areas.

Tap water-agar-glucose-peptone-potassium phosphate-iron citrate-chalk medium: In 24 hours at 30°C, black, spreading, diffuse areas.

Utilizes peptone as a source of nitrogen. Produces the pigment from peptone only if maltose or glucose is present as a source of carbon. When grown in glucose-peptone broth with CaCO<sub>3</sub> at 25° to 30°C, black pigment is produced after several weeks, and the carbonate is changed to calcium gluconate.

Pigment: The pigment causing the brown coloration is an aromatic substance which is blackened by iron salts. Reduces alkaline solutions of silver and mercury, blackening them

Oxidizes mannitol and sorbitol to fructose and sorbose. Does not attack sucrose and fructose. Much gluconic acid is produced. Acid from glucose and maltose. Acetic acid produced from alcohol

Distinctive character: The formation of dark brown to black pigment in media containing a suitable substrate; particularly glucose.

Source: Isolated from beer.

Habitat: Causes light-colored beer to become darker brown. It is a very strong beer-vinegar bacterium. Also found in souring fruits

5. *Acetobacter roseum* Vaughn. (*Bacterium hoshigaki* var. *rosca* Takahashi and Asai, Cent. f. Bakt., II Abt., 82, 1930, 390; *Acetobacter hoshigaki* Bergey et al., Manual, 4th ed., 1934, 39, Vaughn, Wallerstein Lab. Communications, 5, No. 14, 1942, 20) From Latin, *rosa*, rose.

Rods: 0.7 to 0.9 by 1.5 to 1.8 microns, generally occurring singly, at most in pairs, often in chains. Non-motile. Pellicle on fluid media yields no starch or cellulose reaction.

Koji (a mixture of rice and mold spores used to start fermentation of Japanese bread and saké) extract agar colonies: Small, granular, circular, glistening, umbonate, becoming brownish.

Wort agar colonies: Circular, milky-white, becoming brownish in center and yellowish at periphery.

Glucose saké agar: Circular, milky-white, granular, umbonate, entire.

Hoshigaki (dried persimmons) extract agar: Circular, milky-white, granular, becoming yellowish-brown in the center and grayish-white at the periphery.

Koji extract agar streak: Grayish-white, glistening with ciliate margin, becoming purple brown to brown.

Koji extract: Turbid with thin film, ascending on wall of tube.

Bouillon: Turbid with ring formation.

Yeast infusion glucose agar: Colonies similar to those on wort agar.

Yeast infusion glucose broth: Turbid with thin, ascending film.

Red color produced on saké wort agar and all media containing calcium carbonate

Acid from glucose, fructose, galactose, arabinose, glycerol, mannitol, ethyl and propyl alcohol. No acid from maltose, sucrose, lactose, raffinose, dextrin, starch, inulin, sorbitol, glycogen, isodulcitol and methyl alcohol

Forms gluconic acid from glucose.

Aerobic.

Optimum temperatures 30° to 35°C; maximum 40° to 41°C, minimum 10° to 15°C.

Thermal death point 50°C for 5 minutes

Distinctive character: The formation of a rose to red pigment in suitable media; particularly those containing glucose and calcium carbonate.

Source Isolated from fermenting mash of dried persimmons (hoshigaki), and souring figs and dates.

NOTE: Vaughn, Wallerstein Lab Communications, 5, No. 14, 1912, 20, has proposed the name *Acetobacter roseum* to replace the name *Acetobacter hoshigaki*

As originally described, this organism was given the name *Bacterium hoshigaki* var. *rosea* by Takahashi and Asai (*loc. cit.*) without the authors having first named and described the species *Bacterium hoshigaki*. The Japanese word "hoshigaki" has been used in a confusing manner viz. Takahashi and Asai, *loc. cit.* (*Bacterium industrium* var. *hoshigaki*) and Takahashi and Asai, Jour. Agr. Chem. Soc. Japan, 9, 1933, 351 and Cent. f. Bakt., II Abt., 87, 1933, 335 (*Bacterium hoshigaki* var. *glucuronicum* I, II and III). None of these Japanese names are in the form of true binomials.

6. *Acetobacter suboxydans* Kluyver and de Leeuw. (Paper read at the convention of the Dutch Society of Microbiology, Utrecht, December, 1923, see Tijdschrift v. Vergelijkende Geneeskunde, 10, Afl. 2-3, 1921.) From L. *sub*, under, less; Gr. *oxys*, sharp, acid; *dans*, giving, i.e. less acid giving; less oxidizing.

Short rods: Occurring singly or in chains Non-motile. Morphologically like *Acetobacter rancens*.

Forms very thin, hardly visible pellicle on fluid media.

Wort agar colonies: Very small, circular, slightly yellow.

Acid from ethyl alcohol, propyl alcohol, glycol, glucose, glycerol and sorbitol.

Optimum temperature 30°C.

Distinctive character: Partial oxidation of substrates as indicated by the formation of calcium 5-keto gluconate crystals on the surface of agar slants containing glucose and calcium carbonate.

Source: Isolated from spoiled beer.

Habitat: Beer.

7. *Acetobacter oxydans* (Henneberg) Bergey et al. (*Bacterium oxydans* Henneberg, Cent. f. Bakt., II Abt., 3, 1897, 223; *Bacillus oxydans* Migula, Syst. d. Bakt., 2, 1900, 800; Bergey et al., Manual, 1st ed., 1923, 36.) From Gr. *oxys*, sharp, acid; *dans*, giving.

Rods 0.8 to 1.2 by 2.4 to 2.7 microns, occurring singly and in chains. Motile

cells possess a single polar flagellum (Vaughn, Jour. Bact., 46, 1943, 394) The chains show bud-like swellings

Gelatin colonies: Circular, becoming irregular in shape with peculiar ramifications.

Acid from arabinose, fructose, glucose, galactose, sucrose, maltose, raffinose, dextrin, ethyl alcohol, propyl alcohol, erythritol, mannitol, glycol and glycerol No acid from sorbose, lactose, starch, glycogen, inulin, methyl alcohol, isopropyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol, dulcitol and acetaldehyde (Henneberg, Die deutsch Essigind., 2, 1898, 147).

Aerobic

Optimum temperature 18° to 21°C

Distinctive characters Low optimum temperature for growth and oxidation of substrates; and the ability to oxidize a large number of substrates

Habitat: Beer.

Appendix: The following species have been described, but until more comparative studies have been made, no change in nomenclature is recommended or advisable

1. *Acetobacter zaidleri* Beijerinck (*Termobacterium aceti* Zeidler, Cent. f. Bakt., II Abt., 2, 1896, 739, *Bacterium zaidleri* Beijerinck, *Acetobacter zaidleri* Beijerinck, Kral's Sammlung v. Mikroorg., Prague, 1898, 7, *Bacillus zaidleri* Migula, Syst. d. Bakt., 2, 1900, 801, *Acetobacter lindneri* Bergey et al., Manual, 1st ed., 1923, 36) Named for A. Zeidler, who first isolated this species

Rods, occurring singly and in chains, showing large sausage-shaped involution forms. Motile with a single polar flagellum (Zeidler, Cent. f. Bakt., II Abt., 4, 1898, 669).

Wort gelatin Small, circular, slightly granular, yellowish-brown, entire colonies. No liquefaction

Dirty, yellowish-brown pellicle on liquid media.

Wort gelatin slant: Strongly glistening,

transparent, whitish in center, smooth, very weakly liquefied

Potato: Very scant growth

Acid from glucose, ethyl alcohol, propyl alcohol and glycol No acid from arabinose, fructose, galactose, maltose, lactose, raffinose, dextrin, glycogen methyl alcohol, isopropyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol, glycerol, mannitol and acetaldehyde (Henneberg, Die deutsch Essigind., 2, 1898, 147).

Aerobic, facultative.

Optimum temperature 25°C.

Habitat: Beer wort.

2 *Acetobacter acetosum* (Henneberg) Bergey et al. (*Bacterium acetosum* Henneberg, Cent. f. Bakt., II Abt., 3, 1897, 223, Bergey et al., Manual, 1st ed., 1923, 36) From Latin, *acetum*, vinegar.

Rods. 0.4 to 0.8 by 1.0 micron, occurring singly and in chains Non-motile. Stains yellow with iodine.

On beer, yeast water and glucose solutions a firm, coherent, uniform, smooth, white film that becomes folded (Henneberg, Gärungsbakt., 2, 1926, 201).

Acid from glucose, galactose, ethyl alcohol, and propyl alcohol. No acid from arabinose, fructose, sorbose, sucrose, maltose, lactose, raffinose, dextrin, starch, glycogen, inulin, methyl alcohol, isopropyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol, glycerol, erythritol, mannitol, dulcitol and acetaldehyde (Henneberg, Die deutsch Essigind., 2, 1898, 147).

Optimum temperature 25°C, maximum 36°C, minimum 8°C (Henneberg, Cent. f. Bakt., II Abt., 4, 1898, 14).

Habitat: Beer.

3 *Acetobacter ascendens* (Henneberg) Bergey et al. (*Bacterium ascendens* Henneberg, Zeitschr. f. deutsche Essigind., Berlin, No. 10 to 23, 1898, 145, also see Cent. f. Bakt., II Abt., 4, 1898, 933, Bergey et al., Manual, 1st ed., 1923, 37.) From Latin, *ascendo*, pp. *ascendens*, ascending.

Rods, occurring singly, rarely in chains.

Non-motile. Do not give the cellulose reaction with iodine solution.

Glucose gelatin colonies: Dry, white, with white area surrounding the colony.

Fluid cultures have a tough pellicle rising on the wall of the flask.

Acid from ethyl alcohol, propyl alcohol and glycol. No acid from arabinose, fructose, glucose, galactose, sucrose, maltose, lactose, raffinose, dextrin, starch, methyl alcohol, isopropyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol, glycerin, mannitol and acetaldehyde (Henneberg, Die deutsch. Essig-ind., 2, 1898, 147).

Aerobic.

Optimum temperature 31°C.

Habitat: Isolated from vinegar and from red wine.

4. *Acetobacter plicatum* Fuhrmann. (Beihefte z. bot. Centralbl., Orig., 19, 1905, 8) Description given in Cent. f. Bakt., II Abt., 15, 1906, 377. From *plicatus*, folded.

Rods: 0.55 to 0.7 by 0.75 to 0.9 microns when grown on agar at 25° to 30°C. Young streak cultures 0.4 to 0.6 by 1.4 to 1.6 microns with homogeneous staining when grown on beef-extract-gelatin at 22°C. 0.5 by 1.5 to 1.7 microns with uneven staining (polar) when grown on wine gelatin. At about 40°C the organisms form swollen and greatly elongated forms. Non-motile.

Agar slant: Pale yellowish, translucent growth.

Alcohol-free beer with glucose and sucrose: Turbid with thick pellicles.

Potato: Growth limited.

Ferments alcohol to form acetic acid.

Optimum temperature 28° to 30°C.

Habitat: Wine.

5. *Acetobacter aceti*genum (Henneberg) Bergey et al. (*Bacterium aceti*genum Henneberg, Cent. f. Bakt., II Abt., 4, 1898, 14; *Bacillus aceti*genum Migula, Syst. d. Bakt., 2, 1900, 801; Bergey et al., Manual, 1st ed., 1923, 35.) From Latin, producing vinegar.

Rods, occurring singly and in pairs. 0.8 to 1.2 by 1.2 to 1.4 microns. Motile. Cells give a cellulose reaction with H<sub>2</sub>SO<sub>4</sub> and iodine.

Glucose gelatin colonies: Raised, grayish, slimy.

Fluid cultures show a tough, slimy pellicle.

Acid from glucose, ethyl alcohol, propyl alcohol and glycol. No acid from arabinose, fructose, galactose, sorbose, sucrose, maltose, lactose, raffinose, dextrin, starch, glycogen, inulin, methyl alcohol, isopropyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol, glycerol, erythritol, mannitol, dulcitol and acetaldehyde (Henneberg, Die deutsch. Essig-ind., 2, 1898, 147).

Aerobic.

Optimum temperature 33°C. Thermal death point 43° to 45°C for 5 minutes.

Habitat: Vinegar.

6. *Acetobacter industrium* (Henneberg) Bergey et al. (*Bacterium industrium* Henneberg, Zeitschr. f. deutsche Essigindustrie, Berlin, 1898; Cent. f. Bakt., II Abt., 4, 1898, 933; *Bacillus industrius* Migula, Syst. d. Bakt., 2, 1900, 801; Bergey et al., Manual, 1st ed., 1923, 36.) From Latin *industrius*, diligent.

Rods 0.3 to 0.8 by 2.4 to 20 microns, occurring singly and in chains. No distinct color produced with iodine. Motile.

Forms pellicle on fluid culture media.

Acid from arabinose, fructose, glucose, galactose, sucrose, maltose, lactose, raffinose, starch, dextrin, ethyl alcohol, propyl alcohol, glycol, glycerol and mannitol. No acid from isopropyl alcohol, butyl alcohol, isobutyl alcohol, amyl alcohol and acetaldehyde (Henneberg, Die deutsch. Essig-ind., 2, 1898, 147).

Aerobic.

Optimum temperature 23°C. Maximum 35°C. Minimum 8°C.

Habitat: Beer wort.

7. *Bacterium schuezenbachii* Henneberg. (Die deutsche Essigind., No. 11-18, 1906; also Cent. f. Bakt., II Abt., 17, 1906, 790.) Named for Schützenbach, the inventor of the German quick vinegar process.

Rods: 0.3 to 0.4 by 1.0 to 3.6 microns, occurring singly, in pairs and chains. The cells are round, oval or elongated, not infrequently sickle-shaped or irregularly bent with rounded or pointed ends. Not stained with iodine. Non-motile.

Wort gelatin colonies: Round, shiny, transparent with yellowish brown centers.

A non-coherent film produced on the surface of liquid media.

Acid from arabinose, fructose, glucose, galactose, maltose, lactose, dextrin, ethyl alcohol, propyl alcohol, glycerol and erythritol. Small amount of acid from sucrose and raffinose. No acid from mannitol (Henneberg, Handbuch d. Gärungs-bakt., 2, 1925, 239).

Temperature relations. Optimum 25° to 27.5°C. Scant growth at 34° to 35°C and 13° to 15°C. No growth at 37° and 7.5°C.

Source: Isolated from vinegar in the quick vinegar process.

Habitat. Produces acetic acid in quick vinegar process.

8. *Bacterium xylinoides* Henneberg (Die deutsche Essigind., No. 11 to 18, 1906; also Cent. f. Bakt., II Abt., 17, 1906, 791.) From Greek, woody.

Rods: 0.5 to 0.8 microns (round cells) and 0.5 to 1.2 microns (long forms), occurring singly, in pairs or chains, cells round and as short and long rods. The thick membrane like that produced by *Acetobacter xylinum* gives the reaction for cellulose with iodine and sulfuric acid, but the thin membrane does not.

Wort gelatin. Colonies are produced like drops of water, often with light brown kernels in the center.

Wort gelatin streak: Growth transparent at first, later whitish.

Three types of membrane on fluid media are formed by this species and all three may even be found on a culture at one time. A thin, firm, coherent membrane like that of *Bacterium orleanense* may be formed or one that is voluminous, scumlike (like coagulated egg-white), coherent, somewhat slimy and finally thick like that of *Bacterium xylinum*. Also a membrane may be formed that is intermediate in type.

Acid from arabinose, glucose, galactose, sucrose, maltose, ethyl alcohol, propyl alcohol, glycerol and erythritol. Small amount of acid from fructose and mannitol.

Temperature relations: Optimum 28°C. Slight growth at 14°C. No growth at 6°C.

Source. Isolated from wine vinegar from the Rhine and other sections.

Habitat: Found in vinegar made by the Orleans method.

9. *Bacterium orleanense* Henneberg. (Die deutsche Essigind., No. 11-18, 1906; also Cent. f. Bakt., II Abt., 17, 1906, 792.) Latinized, of Orleans.

Rods: 0.4 to 0.5 by 1.2 to 2.1 microns, occurring singly or in chains. The cells are round, elongated or as involution forms, with straight or curved cells appearing. Not stained with iodine. Non-motile.

Wort gelatin. Colonies irregular in form, whitish in color, about 1 mm. in diameter in 2 days.

Wort gelatin streak: Growth often slimy, transparent, liquid mass with yellowish-brown sediment.

Wort agar streak: Some strains form isolated, moist, slimy, transparent colonies and on the water of condensation isolated whitish colonies are formed. Other strains form a coherent, transparent coating with a light brown precipitate later and individual, distinct, round colonies of the same color.

Characteristic of this species is the firm coherent film on the surface of liquid media.

Acid from arabinose, glucose, galactose, maltose, lactose, raffinose, dextrin, ethyl alcohol, propyl alcohol, glycerol, erythritol and mannitol. Small amount of acid from fructose and sucrose (Henneberg, Handbuch d. Gärungsbakt., 2, 1926, 239).

Temperature relations: Optimum 20° to 30°C. Slight growth at 35° to 36°C and 14° to 15°C. No growth at 39° and at 7° to 8°C.

Source: Isolated from vinegar in the quick vinegar process.

Habitat: Can be used both in the quick or German process and the Orleans method of making vinegar.

10. *Bacterium vini acetati* Henneberg. (Die deutsche Essigind., No. 11-18, 1906; also Cent. f. Bakt., II Abt., 17, 1906, 797) From Latin *vinum*, wine and *acetum*, vinegar.

Rods: 0.3 to 0.8 by 0.8 to 2.0 microns, occurring singly, in pairs and sometimes as short chains of three; cell round, oval or slightly elongated, and rarely moderately long forms. Streptococcus-like cells are found on older agar cultures and spindle forms in beer gelatin with 10 per cent sucrose.

Wort gelatin: Round, moist, shiny, transparent colonies with whitish sediment in the center.

The film on liquid media is not strongly coherent and the liquid is cloudy.

Acid from arabinose, fructose, glucose, galactose, sucrose, maltose, raffinose, dextrin, ethyl alcohol, propyl alcohol, glycerol and erythritol. No acid from lactose (Henneberg, Handbuch d. Gärungsbakt., 2, 1925, 239).

Optimum temperature 28° to 33°C

Source: Wine vinegar.

Habitat: Found in vinegar made by the Orleans method for wine vinegar.

11. *Bacterium curvum* Henneberg. (Die deutsche Essigind., No. 11-18, 1906; also Cent. f. Bakt., II Abt., 17, 1906, 791) From Latin, *curvus*, bent.

Rods: 0.4 to 0.5 by 2.0 to 2.4 microns,

occurring singly or in pairs, cells usually oval or elongated, not infrequently sickle-shaped, with rounded or pointed ends. Not stained with iodine solution. Non-motile.

Wort gelatin: Transparent, round colonies with raised center and edge, frequently whitish and dry.

A non-coherent scanty pellicle is formed on the surface of liquid media which sinks readily and the liquid is quite turbid.

Forms round white islands on the surface of wort with 3 per cent alcohol.

In old cultures on beer are to be found numerous smooth light brown raised colonies about 1 mm in diameter on the uniform transparent base of the surface membrane.

Acid from arabinose, glucose, raffinose, dextrin, ethyl alcohol, propyl alcohol, glycerol and erythritol. Small amount of acid from fructose, galactose and mannitol. No acid from sucrose, maltose and lactose (Henneberg, Handbuch d. Gärungsbakt., 2, 1925, 239).

Temperature relations: Optimum 25° to 30°C. Scant growth at 16° to 17°C. No growth at 7° to 8°C. Growth at 35°C. No growth at 39°C.

Source: Isolated from vinegar in the quick vinegar process.

Habitat: Produces acetic acid in the quick vinegar process.

12. *Acetobacter viscosum* Shimwell (*Bacterium aceti viscosum* Day and Baker, Cent. f. Bakt., II Abt., 36, 1913, 433; *Bacillus aceti viscosum* Day and Baker, *ibid.*, 437; Also see Baker, Day and Hulton, Jour. Inst. Brewing, 1, 1912, 651; Shimwell, Jour. Inst. Brewing, 42 (N. S. 32), 1936, 586.) From Latin, *viscosus* or slimy.

Rods: 0.4 by 1.2 microns which produce ropiness in beer. No capsules observed. Non-motile as a rule. Weakly Gram-positive

Source: From ropy beer.

13 *Acetobacter capsulatum* Shimwell. (Jour. Inst. Brewing, 42 (N. S. 32), 1936, 585.) From Latin, capsulated.

Coccoid rods, 0.8 to 1.0 micron in malt extract media. 0.6 to 1.5 microns in other media. Produce ropiness in beer. Capsulated. Motile. Gram-negative.

Source: Fromropy beer.

14 *Acetobacter gluconicum* (Hermann).\* (*Bacterium gluconicum* Hermann, Biochem. Zeit., 192, 1928, 198, also see Hermann, Biochem. Zeit., 205, 1929, 297 and Hermann and Neuschul, Biochem. Zeit., 233, 1931, 129.)

It is unfortunate that an organism so well described must be placed with other species of uncertain standing. However, this organism is so closely related to the other organisms described in the literature that further study is necessary.

Source: From kombucha, a mixture of fungi and bacteria from tea infusions

15. *Acetobacter turbidans* Cosbie, Tošić and Walker. (Jour. Inst. Brewing, 48, 1942, 82.)

This beer vinegar bacterium is characterized by the production of intense turbidity in beer and ale. The description given does not, at present, warrant recognition of the organism as a new species.

Source: From beer.

16. *Bacterium dihydroxyacetonicum* Virtanen and Bärlund. (Biochem. Zeit., 169, 1926, 170.)

There is no adequate description of this bacterium, and it is doubtful whether it can be properly evaluated since various species of *Acetobacter* also possess the ability to produce dihydroxyacetone from glycerol. Consideration of this as a *nomen nudum* was indicated by Virtanen to Vaughn in a personal communication in 1938.

Source: From beet juice.

17 *Acetobacter peroxydans* Visser 't Hooft. (Inaug. Diss., Delft, 1925, 98.)

The exact taxonomic position of this bacterium will not be clear until further comparative studies have been made.

Source: From hydrogen peroxide solutions.

#### Genus V *Protaminobacter* den Dooren de Jong.†

(Bijdrage tot de kennis van het mineralisatieproces Thesis, Rotterdam, 1926, 159.) From M. L., protamine and Latin, *bastrum*, rod

Cells motile or non-motile Capable of dissimilating alkylamines Pigmentation frequent. Soil or water forms

The type species is *Protaminobacter alboflavum* den Dooren de Jong.

#### Key to the species of genus *Protaminobacter*.

I. Non-motile. Gelatin colonies light yellow to colorless.

1. *Protaminobacter alboflavum*

II. Motile Gelatin colonies red

2 *Protaminobacter rubrum*.

1. *Protaminobacter alboflavum* den Abt., 71, 1927, 218.) From Latin *albus*, white; *flavus*, yellow.

Dooren de Jong (Thesis, Rotterdam, 1926, 159; also see Cent. f. Bakt., II Rods-Non-motile. Gram-negative

\* It is uncertain at present who first used this combination.

† Prepared by Prof. D. H. Bergey, Philadelphia, Pennsylvania, June, 1929; further revision by Prof. Robert S. Breed, New York State Experiment Station, Geneva New York, April, 1943.

Gelatin colonies: Circular, dry, light yellow or colorless.

Gelatin stab: No liquefaction.

Agar colonies: Circular, opaque, pigment bright red, yellow, light gray or colorless.

Amine agar colonies: Circular, white to dark yellow.

See table below for list of organic substances utilized.

2. *Protaminobacter rubrum* den Dooren de Jong. (Thesis, Rotterdam, 1926, 159; also see Cent. f. Bakt., II Abt., 71, 1927, 218.) From Latin, *ruber*, red.

Rods: Motile with single polar flagellum (Weaver, Samuels and Sherago, Jour. Bact., 35, 1938, 59). Gram-negative.

Gelatin colonies: Circular, red, dry.

Gelatin stab: No liquefaction.

TABLE I.—Organic Substances Utilized as a Source of Carbon by Varieties of *Protaminobacter alboflavum*

ORGANIC ACIDS	$\alpha$	$\beta$	$\gamma$	$\delta$	AMINO COMPOUNDS	$\alpha$	$\beta$	$\gamma$	$\delta$	AMINES	$\alpha$	$\beta$	$\gamma$	$\delta$

Quinic	+	+	0	0										

Catalase is formed.

Aerobic, facultative.

Optimum temperature 30°C.

Habitat: Soil and water.

NOTE: The author recognizes four varieties of this species which he differentiates on the basis of organic substances attacked (see Table) and pigment produced. Variety  $\alpha$  shows light yellow growth on gelatin, bright red on agar and yellow on amine agar. Variety  $\beta$  is light yellow on gelatin, yellow on agar and dark yellow on amine agar. Variety  $\gamma$  is light yellow on gelatin, light gray on agar and yellow on amine agar. Variety  $\delta$  is colorless on gelatin and agar and white on amine agar.

Agar colonies: Circular, red, opaque.

Amine agar colonies: Circular, dark red.

The following organic acids are attacked: Acetic, lactic,  $\beta$ -oxybutyric, glycerinic, succinic, malonic, formic, methyl formic, glutaric, maleinic, fumaric, malic, tartaric, citric and quinic.

The following amino compounds are attacked: Sarcosin, betain, hippuric acid, asparagine, propionamid, capronamid, lactamid, succinamid, allantoin and uric acid.

Glucose is fermented.

Catalase is formed.

Aerobic, facultative.

Optimum temperature 30°C.

Habitat: Soil and water.

Genus VI. *Mycoplana* Gray and Thornton.\*

(Cent. f. Bakt., II Abt., 73, 1928, 82.) From Greek, *mylēs*, fungus; *planē*, a wanderer or traveller.

Cells branching, especially in young cultures. Frequently banded when stained. Capable of using phenol and similar aromatic compounds as a sole source of energy. Grow well on standard culture media.

Type species *Mycoplana dimorpha* Gray and Thornton.

Key to the species of genus *Mycoplana*.

I. Gelatin not liquefied.

1. *Mycoplana dimorpha*.

II. Gelatin liquefied.

2. *Mycoplana bullata*.

1. *Mycoplana dimorpha* Gray and Thornton. (Cent. f. Bakt., II Abt., 73, 1928, 82.) From Greek, *di*, two; *morphos*, forms.

Short, curved and irregular rods, 0.5 to 0.7 by 1.25 to 4.5 microns, showing branching especially in young cultures. Motile, with long polar flagella. Gram-negative.

Gelatin colonies: Circular, buff, smooth, resinous, entire.

Gelatin stab: No liquefaction. Growth filiform.

Agar colonies: Circular, buff, convex, smooth, glistening, entire.

Agar slant: Filiform, white, convex, glistening, entire.

Broth: Turbid, with surface ring.

Nitrites not produced from nitrates but gas evolved in fermentation tubes.

Starch hydrolyzed.

No acid from carbohydrate media.

Attacks phenol.

Aerobic.

Optimum temperature below 30°C.

Source: One strain isolated from soil.

Habitat: Probably in soil.

2. *Mycoplana bullata* Gray and Thornton (Cent. f. Bakt., II Abt., 73, 1928, 83.) From Latin, *bullatus*, furnished with a boss or knob.

Rods, curved and irregular, branching, 0.8 to 1.0 by 2.25 to 4.5 microns. Motile with polar flagella. Gram-negative.

Gelatin colonies: Circular, buff, smooth, glistening, edge diffuse. Partially liquefied.

Gelatin stab: Saccate liquefaction.

Agar colonies: Circular, white, convex, smooth, glistening, entire.

Agar slant: Filiform, white, convex, smooth, glistening, entire.

Broth: Turbid.

Nitrites not produced from nitrates.

Gas, presumably N<sub>2</sub>, in fermentation tubes.

Starch not hydrolyzed.

No acid from carbohydrate media.

Attacks phenol.

Aerobic.

Optimum temperature below 30°C.

Source: Two strains isolated from soil.

Habitat: Probably in soil.

\* Prepared by Prof. D. H. Bergey, Philadelphia, Pennsylvania, June, 1929.

† The original statements regarding the flagellation of these species are contradictory. The first reads "Polar, peritrichous, the second "Polar or peritrichous". Drawings given usually indicate peritrichous rather than polar flagellation. Further study is needed before these species can be properly placed in relation to other known species.—Editors

TRIBE II. SPIRILLEAE KLUYVER AND VAN NIEL.  
(Cent. f. Bakt., II Abt., 94, 1936, 346.)

More or less spirally curved cells.

*Key to the genera of tribe Spirilleae.*

- I. Generally motile by means of a single polar flagellum.
  - A. Short, bent rods occurring singly or united into spirals.  
Genus I. *Vibrio*, p. 192.
  - B. Slightly curved rods of variable length. Strict anaerobes which reduce sulfates to hydrogen sulfide.  
Genus II. *Desulfovibrio*, p. 207.
  - C. Cells oxidize cellulose forming oxycellulose. Growth on ordinary culture media is feeble.
    1. Long, slightly curved rods with rounded ends.  
Genus III. *Cellvibrio*, p. 209.
    2. Short, curved rods with pointed ends.  
Genus IV. *Cellfalcicula*, p. 211.
- II. Generally motile by means of a tuft of polar flagella. Cells of varying thickness, and length and pitch of spiral, forming either long curves or portions of a turn.
  - A. Oxidize inorganic sulfur compounds. Cells contain free sulfur granules.  
Genus V. *Thiospira*, p. 212.
  - B. Not as above.  
Genus VI. *Spirillum*, p. 212.

*Genus I. Vibrio Müller.\**

(Müller, *Vermium terrestrium et fluviatilium*, 1, 1773, 39; *Pacinia* Trevisan, *Atti d. Accad. Fisio-Medico-Statistica in Milano*, Ser. 4, 3, 1885, 83; *Microspira* Schroeter in Cohn, *Kryptogamen-Flora von Schlesien*, 3, 1, 1886, 168; *Pseudospira* De Toni and Trevisan, *Sylloge Fungorum*, 8, 1889, 1018; *Photobacterium* Beijerinck, *Arch. néerl. d. sci. exactes*, 23, 1889, 401; *Liquidovibrio* Orla-Jensen, *Cent. f. Bakt. II Abt.*, 22, 1909, 333; *Solidovibrio* Orla-Jensen, *ibid.*; *Dicrospira* Enderlein, *Sitzber. Ges. naturf. Freunde*, Berlin, 1917, 313.) From Latin, *vibro*, vibrate.

Cells short, curved, single or united into spirals. Motile by means of a single polar flagellum which is usually relatively short; rarely, two or three flagella in one tuft. They grow well and rapidly on the surface of standard culture media. Aerobic to anaerobic species. Mostly water forms, a few parasites.

The type species is *Vibrio comma* (Schroeter) Winslow et al.

*Key to the species of genus Vibrio.*

- I. Gelatin liquefied.
  - A. Nitrites produced from nitrates.
    1. Indole is formed.
      - a. Milk not coagulated.
        1. *Vibrio comma*.
        2. *Vibrio berolinensis*.
      - aa. Milk coagulated.
        3. *Vibrio metschnikovii*.

\* Revised by Prof. D. H. Bergey, Philadelphia, Pennsylvania, April, 1937; partial revision by Capt. Wm. C. Haynes, Sn.C., Fort Bliss, Texas, July, 1943 and by Lt. Col. A. Parker Hitchens, University of Pennsylvania, Philadelphia, Penna., December, 1943.

## 2. Indole not formed.

## a. Milk not coagulated.

4. *Vibrio tyrogenus*.5. *Vibrio xenopus*.

## B. Nitrites not produced from nitrates.

## 1. Indole is formed

## a. Milk coagulated, peptonized

6. *Vibrio piscium*.

## 2. Indole not formed.

## a. Milk acid, coagulated

7. *Vibrio proteus*.8. *Vibrio wolffi*9. *Vibrio sputigenus*.10. *Vibrio liquefaciens*

## aa. Milk not coagulated

## b. Growth on potato thin, barely visible

11. *Vibrio strictus*.

## bb. No growth on potato

12. *Vibrio aquatilis*

## aaa. Action on milk not reported

## b. Acid from glucose Attacks naphthalene.

13. *Vibrio neocisles*

## bb. No acid from carbohydrates Attacks naphthalene

14. *Vibrio cuneatus*

## bbb. No acid from carbohydrates Liquefies agar

15. *Vibrio granii*

## II. Gelatin not liquefied

## A. Nitrites produced from nitrates

## 1. Acid and gas from glucose

16. *Vibrio leonardii*

## 2. Acid but not gas from glucose Liquefies agar.

17. *Vibrio agarliquefaciens*

## B. Nitrites not produced from nitrates

## 1. Acid from glucose

18. *Vibrio cyclosiles*

## 2. No acid from carbohydrates

19. *Vibrio percolans*

## C. Nitrite production not reported

## 1. Requires the addition of ammonium sulfate for growth Ammonium sulfate agar liquefied.

20. *Vibrio andoi*.

## 2. Do not require ammonium sulfate for growth

## a. Indole not formed

## b. Microaerophilic, becoming aerobic.

21. *Vibrio fetus*

## bb. Aerobic, facultative

22. *Vibrio pierantonii*.

1. *Vibrio comma* (Schroeter) Wins-  
low et al. (Kommabacillus, Koch,  
Berliner klin. Wochenschr., 21, 1881,

479; *Spirillum cholerae asiaticae* Zopf,  
Die Spaltpilze, 3 Aufl., 1883, 69, *Vibrio*  
*cholerae asiaticae* Trevisan, Atti d. Accad

Fisio-Med.-Statistica in Milano, Ser. 4, 3, 1885, 84; *Microspira comma* Schroeter, in Cohn, Kryptogamen Flora v. Schlesien, 3, 1, 1886, 163; *Vibrio cholerae* Neisser, Arch. f. Hyg., 19, 1893, 199; *Vibrio cholerae asiaticae* Pfeiffer, in Flügge, Die Mikroorganismen, 2, 1896, 527; Winslow et al., Jour. Bact., 5, 1920, 204; *Bacillus cholerae* Holland, Jour. Bact., 5, 1920, 217; *Bacillus comma* Holland, *ibid.*, 218; *Spirillum cholerae-asiaticae* Holland, *ibid.*, 225; *Vibrio cholerae-asiaticae* Holland, *ibid.*, 226.) From Latin, comma.

Slightly curved rods, 0.3 to 0.6 by 1.0 to 5.0 microns, occurring singly and in spiral chains. Cells may be long, thin and delicate or short and thick. May lose their curved form on artificial cultivation. Motile, possessing a single polar flagellum. Gram-negative.

Gelatin colonies: Small, yellowish-white

Gelatin stab: Rapid napiform liquefaction

Agar colonies: Circular, whitish-brown, moist, glistening, translucent, slightly raised, entire.

Agar slant: Brownish-gray, moist, glistening.

McConkey's medium: Good growth, colonies colorless when young, soon pinkish, medium becomes darker red.

Broth: Slightly turbid, with fragile, wrinkled pellicle and flocculent precipitate.

Peptone water: Characteristic rapid growth, chiefly at surface, where after 6 to 9 hours, a delicate membrane is formed; little turbidity, deposit apparently derived from pellicle (Topley and Wilson, Princip. Bact. and Immun., 2nd ed., 1936, 388) Readily isolated from the surface film of 0.1 per cent peptone water.

Litmus milk: Alkaline at the top and slightly acid at bottom; generally not coagulated; peptonized; reduced

Potato: Dirty-white to yellowish, moist, glistening, spreading.

Blood serum: Abundant growth, sometimes slow liquefaction.

Blood agar: The blood pigment is digested forming a greenish zone around colonies; a true soluble hemolysin is not formed (the El Tor vibrio also digests blood pigment but in addition produces a soluble hemolysin. Otherwise it is said to be indistinguishable from the typical cholera vibrio).

Indole is formed.

Nitrites produced from nitrates.

Cholera-red reaction, which depends on production of indole and reduction of nitrates is positive.

Hydrogen sulfide is formed.

Acid but not gas from glucose, fructose, galactose, maltose, sucrose and mannitol. Slowly from glycerol. Does not attack lactose, inulin or dulcitol.

Group I of Heiberg (Classification of *Vibrio cholerae* and Cholera-like Vibrios. Copenhagen, 1935) ferments mannose and sucrose but not arabinose.

Hydrolyzes starch actively in alkaline media.

High alkali but low acid tolerance; optimum pH 7.6 to 8.0; for isolation on Dieudonne's medium pH 9.0 to 9.6.

Aerobic, grows best in abundant oxygen; under strict anaerobiosis may fail to grow altogether.

Optimum temperature 37°C. Maximum 42°C. Minimum 14°C.

Source: From intestinal contents of cholera patients in Egypt and India

Habitat: Intestinal contents of cholera patients and carriers.

The relationships existing among the cholerogenic and non-pathogenic water vibrios, although studied intensively, have not yet been completely defined. As a working scheme, based on somatic (O) and flagellar (H) antigen studies, Gardner and Vankatraman (Jour. Hyg., 55, 1935, 262-282) suggest the following

## Cholera group of vibrios.

(Biochemically similar. Common H antigen.)

Linton (Bact. Rev., 4, 1940, 275) has outlined a classification of the vibrios based upon their protein and polysaccharide structures. Using chemical methods, it was found that one polysaccharide and one protein was commonly obtained from each strain of vibrio; when exceptions occurred, it was invariably noted that the strain was undergoing dissociation. Given a single protein and polysaccharide in each vibrio, it was possible to divide the strains into six groups, which were numbered in the order of their discovery as shown in the table

*A chemical grouping of the cholericogenic and water vibrios*

Group	Protein Type	Polysaccharide Type
I	I	I
II	I	II
III	II	II
IV	II	I
V	II	III
VI	I	III

The strains of Groups I and II possess the same protein and different polysaccharides. These are derived from cases of cholera and have the serological

and biochemical characteristics of O-Group I, *Vibrio cholera*. Group I strains are more common than those of Group II, which have, however, been isolated from epidemics with a high mortality. The phospholipid fraction is common to both types when isolated in the early part of an epidemic, but is not found in strains of other groups. The harmless water vibrios, which are so heterogeneous serologically (Taylor and Ahuja, Indian Jour. Med Res., 26, 1938, 8-32) form a single chemical group with a homogeneous structure. They fall into Group III, which differs in its protein structure from the authentic cholera vibrios, and resembles Group II in its polysaccharide. The vibrios of Group IV, which came from El Tor and from chronic vibrio carriers are believed on epidemiological grounds to be harmless, although serological methods have failed to distinguish them from cholericogenic vibrios. Group V, which, like III and IV, contains protein II, consists, like Group IV, of strains from chronic vibrio carriers. Group VI strains are only rarely isolated in nature and representatives of this group are generally found among collections of old laboratory strains. They appear to be the result of polysaccharide variation from Group I

after long-continued growth on artificial media.

2 *Vibrio berolinensis* Neisser. (Arch. f. Hyg., 19, 1893, 200; *Microspira berolinensis* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 33.) From M. L., the genitive of *Berolina*, the Latin name for Berlin

Curved rods, somewhat smaller than *Vibrio comma*. Frequently occurring in pairs. Motile, possessing a polar flagellum. Pleomorphic. Gram-negative.

Gelatin colonies: Small, grayish, slightly granular, fragmented.

Gelatin stab: Slow, napiform liquefaction.

Agar slant: Grayish-yellow, moist, glistening

Broth: Turbid, with gray pellicle.

Litmus milk: No coagulation, no acid.

Potato: Brownish streak.

Indole is formed

Nitrites produced from nitrates.

Not pathogenic for mice, pigeons or guinea pigs.

Aerobic, facultative.

Optimum temperature 37°C. Minimum above 10°C. Maximum less than 60°C.

Source: Isolated from filtered Spree river water.

3. *Vibrio metschnikovii* Gamaléia. (Gamaléia, Ann. Inst. Pasteur, 2, 1888, 482; *Pacinia metschnikoffi* Trevisan, I generi e le specie delle Batteriacee, 1889, 23; *Spirillum metschnikovi* Sternberg, Man. of Bact., 1893, 511, *Vibrio nordhafen* Pfuhl, Ztschr. f. Hyg., 22, 1894, 234; *Microspira metschnikoffii* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 33.) Named for Metschnikoff, Russian bacteriologist.

Probable synonyms *Vibrio schuylkiliensis* Abbott, Jour. Exp. Med., 1, 1896, 424 (*Microspira schuylkiliensis* Chester, Manual Determ. Bact., 1901, 334); *Vibrio danubicus* Heider, Cent. f.

Bakt., 14, 1893, 341 (*Microspira danubica* Migula in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 33; *Spirillum danubicum* Holland, Jour. Bact., 5, 1920, 225).

Curved rods, somewhat shorter and thicker than *Vibrio comma*. Motile. Gram-negative.

Gelatin colonies: Like those of *Vibrio comma*.

Gelatin stab: Rapid, napiform liquefaction.

Agar slant: Yellowish, plumose, moist, glistening.

Broth: Turbid, with thin, white pellicle.

Litmus milk: Acid, coagulated (eighth day); not peptonized.

Potato: Delicate, brownish growth.

Indole is formed.

Nitrites produced from nitrates.

Pathogenic for pigeons, fowls, and guinea pigs.

Aerobic, facultative.

Optimum temperature 37°C. Maximum less than 45°C.

Source: Isolated from fowl dead of a choleraic disease.

Habitat: The intestinal contents of chickens, pigeons and other animals suffering from a cholera-like disease.

4 *Vibrio tyrogenus* (Flügge) Holland (Käsespirillen, Deneke, Deutsch. med. Wochenschr., 11, 1885, 33; *Spirillum tyrogenum* Flügge, Die Mikroorganismen, 2 Aufl., 1886, 386; *Pacinia denekei* Trevisan, I generi e le specie delle Batteriacee, 1889, 23; *Microspira tyrogena* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1a, 1895, 33; Holland, Jour. Bact., 5, 1920, 225, *Vibrio denekei* Hauduroy et al., Dict. d. Bact. Path., 1937, 541.) From Greek *tyros*, cheese, *genes*, produced from.

Curved rods, rather smaller and more slender than *Vibrio comma*, often very long, closely wound spirals. Motile, possessing a polar flagellum. Gram-negative

Gelatin colonies: Small, gray, granular, entire.

Gelatin stab: Rapid, saccate liquefaction.

Agar slant: Yellowish-white, plumose, glistening.

Broth: Turbid.

Litmus milk: Not coagulated.

Potato: No growth.

Indole not formed.

Slight production of nitrites from nitrates.

Aerobic, facultative.

Optimum temperature 30°C.

Source: Isolated from cheese.

5. *Vibrio xenopus* Schrire and Greenfield (Trans. Royal Soc. S. Africa, 17, 1930, 309.) From *Xenopus*, a genus of African toads.

Spiral forms, occurring singly and in pairs. Non-motile. Gram-negative.

Gelatin stab: Slow, crateriform liquefaction.

Agar colonies: Small, white, glistening, slimy, entire.

Agar slant: Grayish-white, slimy, entire.

Broth: Turbid with flocculent sediment.

Litmus milk: Unchanged.

Potato: Not reported.

Indole is not formed.

Nitrites are produced slowly from nitrates.

Blood serum is peptonized.

Starch is not hydrolyzed.

Acid from glucose, fructose, maltose, glycerol and sorbitol.

Aerobic, facultative.

Optimum temperature 37°C.

Source: Found in abscess of pectoral muscle of African toad.

6. *Vibrio piscium* David. (Cent. f. Bakt., I Abt., Orig., 102, 1927, 46.) From Latin *piscis*, fish.

Curved rods: 0.3 to 0.5 by 2.0 microns. Motile with a single polar flagellum. Gram-negative.

Gelatin colonies: Circular, granular, opaque.

Gelatin stab: Napiform liquefaction.

Agar colonies: Yellowish, circular, smooth, entire, iridescent.

Agar slant: Light yellow, transparent streak.

Broth: Slight turbidity, with thin pellicle.

Litmus milk: Soft coagulum. Peptonized, alkaline.

Potato: Brownish-red streak.

Indole is formed.

Nitrites not produced from nitrates.

Hydrogen sulfide formed.

No action in sugar media.

Pathogenic for frogs.

Aerobic, facultative.

Optimum temperature 18° to 20°C.

Habitat: Causes epidemic infection in fish.

7. *Vibrio proteus* Buchner (Kombacillus der cholera nostras, Finkler and Prior, Deutsche med. Wochenschr., 1884, 632; Buchner, Sitzungsber. d. Gesell. f. Morph. u. Physiol., München, Heft 1, 1885, 10; *Pacinia finkleri* Trevisan, Atti d. Accad. Fisio-Medico-Statistica in Milano, Ser. 4, 3, 1885, 84; *Microspira finkleri* Schroeter, in Cohn, Kryptogamen-Flora von Schlesien, 3, 1, 1886, 168, *Spirillum finkleri* Crookshank, Man. of Bact., 3rd ed., 1890, 282; *Microspira protea* Chester, Manual of Determinative Bacteriology, 1901, 338, *Vibrio finkleri* Holland, Jour. Bact., 5, 1920, 225.) From Greek, *Proteus*, a marine deity who had the power of assuming any shape he chose.

Curved rods: 0.4 to 0.6 by 2.4 microns, often pointed at both ends. Motile, possessing a polar flagellum. Gram-negative.

Gelatin colonies: Small, gray, circular, granular, entire.

Gelatin stab: Rapid, saccate liquefaction.

Agar slant: Dirty grayish, plumose.

Broth: Turbid, with fetid odor.

Litmus milk: Slightly acid; coagulated; peptonized.

Potato: Grayish, slimy layer.

Indole not formed.

Nitrites not produced from nitrates.

Aerobic, facultative.

Optimum temperature 30°C.

Source: Isolated from feces of patients suffering from cholera nostras.

Habitat: Intestinal contents in cholera nostras and cholera infantum.

8. *Vibrio wolfei* (Migula) Bergey et al. (*Bacillus choleroïdes* Wolf, Münch. med. Wochenschr., 40, 1893, 693; *Microspira wolfei* Migula, Syst. d. Bakt., 2, 1900, 1001; not *Microspira choleroïdes* Migula, loc. cit., 992; Bergey et al., Manual, 1st ed., 1923, 80) Named for Wolf, who first isolated this organism.

Curved rods and S-shaped forms. Motile. Gram-negative

Gelatin colonies: Small, grayish-white, spreading

Gelatin stab: Infundibuliform liquefaction.

Agar slant: Gray, moist layer.

Broth: Turbid, with gray pellicle

Litmus milk: Acid; coagulated.

Potato: Yellowish-white layer.

Blood serum: Rapid liquefaction.

Indole not formed.

Nitrites not produced from nitrates.

Aerobic, facultative.

Optimum temperature 37°C.

Source: Isolated from cervical secretions in chronic endometritis.

9. *Vibrio sputigenus* (Migula) Bergey et al. (*Vibrio aus Sputum*, Brix, Hyg. Rundschau, 4, 1894, 913; *Microspira sputigena* Migula, Syst. d. Bakt., 2, 1900, 981; Bergey et al., Manual, 1st ed., 1923, 80.) From Latin, *sputo* (sputus), sputum; -genes, produced from.

Slightly curved rods, about the same size and form as *Vibrio comma*, occurring singly, occasionally three or four in a chain. Motile. Possessing a polar flagellum. Gram-negative.

Gelatin colonies: Small, circular, slightly granular, yellowish, becoming brownish.

Gelatin: Crateriform liquefaction.

Agar slant: Grayish-white, moist.

Broth: Turbid, no pellicle formed.

Litmus milk: Acid; coagulated.

Potato: Thin, gray layer, spreading.

Indole not formed.

Nitrites not produced from nitrates.

Aerobic, facultative.

Optimum temperature 37°C.

Source: Isolated from sputum.

10. *Vibrio liquefaciens* (Migula) Bergey et al. (Bonhoff, Arch. f. Hyg., 19, 1893, 218; *Microspira liquefaciens* Migula, Syst. d. Bakt., 2, 1900, 990; Bergey et al., Manual, 1st ed., 1923, 81.) From Latin, *liquefacio*, to make liquid.

Comma and S-shaped rods. Motile. Gram-negative.

Gelatin colonies: Circular, with irregular margin, surrounded by a rose-colored zone.

Gelatin stab: Slow, napiform liquefaction.

Agar slant: Smooth, grayish, plumose.

Broth: Turbid, with heavy grayish pellicle.

Litmus milk: Acid; coagulated.

Potato: Moist, brownish layer.

Indole is not formed.

Nitrites not produced from nitrates.

Aerobic, facultative.

Optimum temperature 37°C.

Habitat: Water.

11. *Vibrio strictus* Kutscher. (Ztschr. f. Hyg., 19, 1895, 469.) From Latin *stringo* (*strictus*), constricted.

Markedly curved rods, of about twice the size of *Vibrio comma*. Motile. Gram-negative.

Gelatin colonies: Small, circular, yellowish, with serrate margin.

Gelatin stab: Slow, napiform to saccate liquefaction.

Agar slant: Growth plumose, moist

Broth: Turbid, with gray pellicle.

Litmus milk: Not coagulated.  
 Potato: Thin, barely visible layer.  
 Blood serum is slowly liquefied.  
 Indole is not formed.  
 Nitrites not produced from nitrates.  
 Pathogenic for guinea pigs.  
 Aerobic, facultative.  
 Optimum temperature 37°C.  
 Habitat: Water.

12 *Vibrio aquatilis* Günther. (Deutsche med. Wochenschr., 1892, 1124; *Microspira aquatilis* Migula, System der Bakterien, 2, 1900, 993.) From Latin, *aquaticus*, living in water

Curved rods, like *Vibrio comma*  
 Motile, possessing a polar flagellum  
 Gram-negative.

Gelatin colonies: Circular, brownish,  
 finely granular, entire

Gelatin stab: Crateriform liquefaction

Agar slant: Moist, grayish, glistening

Broth: Slightly turbid.

Litmus milk: Not coagulated

Potato: No growth

Indole not formed

Nitrites not produced from nitrates

Aerobic, facultative

Optimum temperature 30°C

Habitat: Water.

13. *Vibrio neoclystes* Gray and Thornton. (Gray and Thornton, Cent. f. Bakt., II Abt., 73, 1928, 92) From Greek *neos*, new and *kistē* box or ark. Here used as the equivalent of Newark, the name of a city in England

Curved rods. 0.5 to 1.0 by 1.0 to 4.0 microns. Motile with one to three polar flagella. Gram stain not recorded.

Gelatin colonies: Liquefied

Gelatin stab: Liquefied. Medium red-dened.

Agar colonies: Circular or amoeboid, buff to brownish, convex, smooth, glistening, entire.

Agar slant: Filiform, fluorescent, raised, smooth, glistening, undulate.

Broth: Turbid.

Nitrites not produced from nitrates

Starch not hydrolyzed.

Acid from glucose.

Attacks naphthalene.

Aerobic, facultative.

Optimum temperature.

Habitat: Soil.

14 *Vibrio cuneatus* Gray and Thornton. (Gray and Thornton, Cent. f. Bakt., II Abt., 73, 1928, 92.) From Latin, *cuneo* (*cuneatus*) wedge.

Curved rods: 1.0 by 1.0 to 3.0 microns, the cells tapering at one extremity. Motile with one to five polar flagella. Gram-negative.

Gelatin colonies: Liquefied.

Gelatin stab: Liquefied

Agar colonies: Circular to amoeboid, white to buff, flat to convex, smooth, translucent, border entire.

Agar slant: Filiform, whitish, smooth, glistening.

Indole not recorded.

Nitrites not produced from nitrates

Starch not hydrolyzed

No acid from carbohydrate media.

Attacks naphthalene

Aerobic, facultative

Optimum temperature 30° to 35°C.

Source: One strain isolated from soil from Rothamsted, England.

Habitat: Soil

15 *Vibrio granli* (Lundestad) Stanier. (*Bacterium granli* Lundestad, Cent. f. Bakt., II Abt., 75, 1928, 330; *Achromobacter granli* Bergey et al., Manual, 3rd ed., 1930, 222, Stanier, Jour. Bact., 42, 1941, 538) Named for Prof. H. H. Gran, who first detected agar-liquefying bacteria.

Rods 0.6 to 0.8 by 1.4 to 2.4 microns, with rounded ends, occurring singly, in pairs, and at times in short chains. Motile. Polar flagellate (Stanier, loc. cit.). Gram-negative.

Fish-gelatin colonies: Punctiform, black, glistening.

Fish-gelatin stab: Slow, crateriform liquefaction.

Sea-weed agar colonies: Circular, flat.

opaque, glistening, white, slimy, entire. Agar is dissolved.

Fish-agar slant. Flat, white, elevated, glistening, undulate. Liquefied.

Broth: Turbid with grayish-white, slimy sediment.

Indole not formed.

Nitrites not produced from nitrates.

Starch usually hydrolyzed.

No action on sugars.

Aerobic, facultative.

Optimum temperature 20° to 25°C.

Source: Sea water of Norwegian Coast.

Habitat: Presumably sea water and on sea weeds

16. *Vibrio leonardii* Métalnikov and Chorine. (Ann. d. l'Inst Pasteur, 42, 1928, 1647) Named for Leonard.

Curved rods with rounded ends, 0.5 to 1.0 by 2.0 to 3.0 microns. Motile with 1 to 3 polar flagella. Gram-negative.

Gelatin stab. No liquefaction.

Agar colonies Small, transparent, circular, having a characteristic odor.

Broth. Turbid, with thin pellicle.

Litmus milk No coagulation, acid, with reduction of litmus.

Potato Slight, colorless growth

Indole not formed

Nitrites produced from nitrates

Blood serum not liquefied

Hydrogen sulfide formed.

Acid and gas from glucose, fructose, galactose, lactose, sucrose and mannitol. No acid or gas from maltose or glycerol.

Aerobic, facultative

Optimum temperature 30°C

Habitat: Highly pathogenic for insects as *Galleria mellonella* L. (bee moth), and *Pyrausta nubilalis* Hübn. (European corn borer).

17. *Vibrio agarliquefaciens* (Gray and Chalmers) Bergey et al. (*Microspira agar-liquefaciens* Gray and Chalmers, Ann. Appl Biol., 11, 1924, 325; Manual, 4th ed., 1934, 119.) From Latin, *liquefacio*, liquefying; Malay, *agar*, a jelly from seaweeds.

Short curved rods, usually c-shaped,

with occasional s-shaped and coccoid forms. Cells 2.0 microns long by 0.5 to 0.7 micron broad; 3.0 to 5.0 microns long in division stages. Coccoid forms stained, 0.5 to 0.7 micron long. Motile with a single polar flagellum. Gram stain not reported.

Gelatin stab: Very slight surface growth after one month; the streak then shows a beaded line. No liquefaction.

Agar colonies: Surface colonies appear as a whitish growth in a depression, surrounded by a white ring. The colony is later surrounded by a ring of liquid agar. Deep colonies show a clear area and may be irregular, oval or angular.

Agar slant: A deep groove is cut along the inoculation streak, whitish growth along sides. The gel is later much weakened.

Broth: Slightly turbid. No pellicle.

Acid from glucose, lactose and maltose. No acid from sucrose or glycerine.

Utilizes ammonia salts as a source of nitrogen.

Decomposes cellulose and agar. The presence of one per cent glucose prevents the liquefaction of agar.

Nitrites produced from nitrates.

Starch is hydrolyzed.

Aerobic.

Temperature relations: Optimum 25°C., will grow at 16° but not at 34°C.

Habitat: Soil.

18. *Vibrio cyclosites* Gray and Thornton. (Gray and Thornton, Cent. für Bakt., II Abt., 73, 1923, 92.) From Greek *kyklos*, circle or ring; *sītēō*, to eat; *M. L. cyclosites*, feeding on rings, i.e. ring compounds.

Curved rods: 0.5 to 1.0 by 1.5 to 4.0 microns. Motile with a single polar flagellum. Gram-negative.

Gelatin colonies: Circular, buff to brown, flat, smooth, glistening, entire.

Gelatin stab: No liquefaction.

Agar colonies: Circular to irregular, pale buff (later greenish), smooth, entire.

Agar stab: Filiform, greenish buff, raised, smooth, undulate.

Potato: No growth.

Indole not formed.

Nitrite production not reported.

Blood serum slant: Feeble growth.

No liquefaction.

Nogas from carbohydrates. No change or slightly acid from glucose, lactose and sucrose.

Optimum temperature 37°C. Withstands 55°C for 5 minutes.

Aerobic or microaerophilic

Pathogenesis Causes abortion in cattle.

Source Twenty-two strains isolated from the placentas or fetuses of cows having abortion.

Habitat Causes abortion in cattle

22. *Vibrio pierantonii* (Zirpolo) Meissner. (*Bacillus pierantonii* Zirpolo, Boll. Soc. nat. Napoli, 30, 1918, 206; Meissner, Cent. f. Bakt., II Abt., 67, 1926, 200.) Named for Pierantoni, an Italian bacteriologist

Rods 0.5 by 1.5 microns, with rounded ends. Motile with one to three polar flagella Gram-negative

Gelatin colonies Circular, and irregularly lobulate

Gelatin stab: No liquefaction

Agar colonies: Circular, light green, smooth, entire

Glycerin agar slant. Slightly luminous streak.

Broth: Turbid, with pellicle

Indole not formed

Acid from glucose and maltose. Some strains also attack lactose, sucrose and mannitol.

Best growth in alkaline media

Aerobic, facultative

Optimum temperature 37°C.

Source: Isolated from the photogenic organ of the cephalopod *Sepioida intermedia* Naef

Appendix: \* The following species have also been listed in the literature. Many are inadequately described

*Microspira bonhoffii* Migula. (Bonhoff, Arch. f. Hyg., 19, 1893, 252; Migula, Syst. d. Bakt., 2, 1900, 1008.) From water.

*Microspira canalis* Migula. (*Spirillum saprophiles* γ and *Vibrio saprophiles* γ Weibel, Cent. f. Bakt., 2, 1887, 469; Migula, Syst. d. Bakt., 2, 1900, 1004; *Microspira cloaca* Chester, Man. Determ. Bact., 1901, 341.) Possibly identical with *Microspira saprophiles* Migula, *Microspira weibelii* Migula, *Vibrio surati* Ford, *Vibrio smithii* Ford. From sewage.

*Microspira coprophila* Migula. (Group 3, No. 6, Kutscher, Ztschr. f. Hyg., 19, 1895, 475; Migula, Syst. der Bakt., 2, 1900, 986) From fecal matter.

*Microspira maasei* (v. Hoff) Migula (*Spirillum maasei* v. Hoff, Cent. f. Bakt., I Abt., 21, 1897, 797; Migula, Syst. d. Bakt., 2, 1900, 978.) Possibly a variety of *Vibrio comma* Winslow et al. From Rotterdam tap water.

*Microspira milleri* Migula. (Miller, Deutsche med. Wchnschr., 11, 1885, 133; Migula, Syst. d. Bakt., 2, 1900, 981; *Spirillum milleri* Holland, Jour. Bact., 5, 1920, 225; *Vibrio milleri* Holland, *ibid.*) Probably identical with *Vibrio proteus* according to Migula. From dental caries

*Microspira murmanensis* Issatchenko. (Recherches sur les microbes de l'océan glacial arctique (in Russian), Petrograd, 1914, 240) From sea water.

*Microspira saprophiles* Migula. (*Heu-vibrio* β, Weibel, Cent. f. Bakt., 2, 1887, 469, *Vibrio saprophiles* β Weibel, Cent. f. Bakt., 4, 1888, 225; Migula, Syst. d. Bakt., 2, 1900, 1006; *Microspira weibelii* Chester, Man. Determ. Bact., 1901, 230.) Probably identical with *Microspira cloaca* Chester and *Vibrio surati* Ford. From sewage.

*Microspira tyrosinatica* Beijerinck. (Kon. Akad. Wetenschappen, Amsterdam, 13, 1911, 1068.) From sewage

*Microspira weibelii* Migula. (*Vibrio*

\* Prepared by Mr. Wm. C. Haynes, New York State Experiment Station, Geneva, New York, Jan 1, 1939; Revised by Capt. Wm. C. Haynes, Sn. C., Fort Bliss, Texas, July, 1943.

*saprophiles*  $\alpha$  Weibel, Cent. f. Bakt., 2, 1887, 465; *ibid.*, 4, 1888, 225; Migula, Syst. d. Bakt., 2, 1900, 1005, *Microspira saprophila* Chester, Manual Determ. Bact., 1901, 341; *Vibrio saprophiles* Ford, Textb. of Bakt., 1927, 356 ) Possibly identical with *Microspira cloaca* Chester, *Vibrio surati* Ford, *Vibrio smithii* Ford From sewage

*Spirillum lipoferum* Beijerinck (Cent. f. Bakt., II Abt., 63, 1925, 353; *Chromatium lipoferum* Bergey et al., Manual, 3rd ed., 1930, 531 ) From garden earth and sewage Giesberger (Beiträge zur Kenntnis der Gattung *Spirillum* Ehb., Inaug. Diss., Delft, 1936, 64) regards this organism as a *Vibrio*. Has a single polar flagellum

*Spirillum nasicola* Trevisan (Nasenschleimvibrio, Weibel, Cent. f. Bakt., 2, 1887, 465; Trevisan, I generi e le specie delle Batteriacee, 1889, 24, *Vibrio nasalis* Eisenberg, Bakt. Diag., 3 Aufl., 1891, 213; *Spirillum nasale* Sternberg, Man. of Bact., 1893, 697; *Spirosoma nasale* Migula, in Engler and Prantl, Die natürl. Pflanzenfam., 1, 1 a, 1895, 31.) From human nasal mucus.

*Spirillum parvum* Esmarch. (Cent. f. Bakt., I Abt., Orig., 52, 1902, 565, also see Zettnow, *ibid.*, 78, 1916, 1, *Vibrio parvus* Lehmann and Neumann, Bakt. Diag., 4 Aufl., 2, 1907, 491 ) From decaying organic matter.

*Vibrio albensis* Lehmann and Neumann (Elbe vibrio, Dunbar, Deutsch. med. Wochenschr., 19, 1893, 799, Lehmann and Neumann, Bakt. Diag., 1 Aufl., 2, 1896, 340; *Microspira dunbari* Migula, Syst. d. Bakt., 2, 1900, 1013; *Photospirillum dunbari* Miquel and Cambier, Traité de Bact., Paris, 1902, 881; *Photobacterium dunbari* Ford, Textb. of Bakt., 1927, 621 ) From water of the river Elbe. Phosphorescent

*Vibrio amylocella* Gray. (Canad. Jour. Res., 17, 1939, 154 ) Decomposes cellulose. Produces glucose from starch. From soil.

*Vibrio anguillarum* Bergman. (Ber. a. d. k. Bayr. Biolog. Versuchstat., Mün-

chen, 2, 1909.) From an infectious disease of eels.

*Vibrio aureus* Weibel. (Weibel, Cent. f. Bakt., 4, 1888, 225, 257, 281; *Spirillum aureum* Trevisan, I generi e le specie delle Batteriacee, 1889, 24, *Spirillum aureum* Sternberg, Man. of Bact., 1893, 700, *Spirosoma aureum* Migula, Syst. d. Bakt., 2, 1900, 953 ) Possibly identical with *Vibrio flarus* Weibel and *Vibrio flavescens* Weibel. From sewage.

*Vibrio beijerinckii* Stanier. (Jour. Bact., 42, 1941, 527-554.) Marine agar-digesting vibrio.

*Vibrio buccalis* Prévot (Vibrien B, Repaci, Compt. rend. Soc. Biol., Paris, 1909, 630; Prévot, Man. de Classif. des Bact. Anaér., Paris, 1940, 82 ) Anaerobe From the buccal cavity.

*Vibrio bulbosa* Kalniņš (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 237.) Decomposes cellulose From soil.

*Vibrio cardii* Klein (Cent. f. Bakt., I Abt., Orig., 53, 1905, 173 ) Possibly identical with *Vibrio cuneatus* Gray and Thornton and *Vibrio marinus* Ford. From the mussel (*Cardium edule*)

*Vibrio castra* Kalniņš (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 241.) Decomposes cellulose From soil.

*Vibrio choleroideus*  $\alpha$  and  $\beta$  Bujwid. (Cent. f. Bakt., 13, 1893, 120; *Microspira choleroideus* Migula, Syst. d. Bakt., 2, 1900, 992 ) Probably a less vigorous strain of *Vibrio comma* Winslow et al. according to Chester, Man. Determ. Bact., 1901, 337. From water

*Vibrio chrysanthemoides* Lehmann and Neumann. (Spirillum-like organism, Jones, Cent. f. Bakt., II Abt., 14, 1904, 450, Lehmann and Neumann, Bakt. Diag., 4 Aufl., 2, 1907, 493.) From five samples of tap water and sewage.

*Vibrio crassus* (Veillon and Repaci) Prévot (*Spirillum crassum* Veillon and Repaci, Ann. Inst. Past., 26, 1912, 306; Prévot, Man. de Classif. des Bact. Anaér., Paris, 1940, 85.) Anaerobe From the buccal cavity.

*Vibrio crassus* var. D, Prévot.

D, Repaci, Ann. Inst. Past., 26, 1912, 550; Prévot, Man. de Classif. des Bact. Anaér., Paris, 1910, 86.) Anaerobe. From the buccal cavity.

*Vibrio crasteri* Hauduroy et al. (Craster, in Violle, Le Choléra, Masson édit., 1919, Hauduroy et al., Dict. d. Bact. Path., 1937, 541.) Isolated from healthy persons. Resembles *Vibrio comma*.

*Vibrio cucumis* Kalniņš. (Latvijas Universitātes Raksti, Serija I, No 11, 1930, 213.) Decomposes cellulose. From soil.

*Vibrio devorans* Beijerinck. (Cent. f. Bakt., II Abt., 11, 1903, 598.) From water.

*Vibrio drennani* Chalmers and Waterfield. (Drennan, Jour. Inf. Dis., 14, 1914, 251; Chalmers and Waterfield, Jour. Trop. Med., 19, 1916, 165.) Colonies white, turning dark brown. From feces.

*Vibrio flavescens* Weibel. (Cent. f. Bakt., 4, 1888, 225, 257, 281; *Spirillum flavescens* Trevisan, I generi e le specie delle Batteriacee, 1889, 24; *Spirillum flavescens* Sternberg, Man. of Bact., 1893, 700; *Spirosoma flavescens* Migula, Syst. d. Bakt., 2, 1900, 959.) Possibly identical with *Vibrio aureus* Weibel and *Vibrio flavus* Weibel. From sewage.

*Vibrio flavus* Weibel. (Cent. f. Bakt., 4, 1888, 225, 257, 281; *Spirillum flavum* Trevisan, I generi e le specie delle Batteriacee, 1889, 24; *Spirillum flavum* Sternberg, Man. of Bact., 1893, 700; *Spirosoma flavum* Migula, Syst. d. Bakt., 2, 1900, 959.) Possibly identical with *Vibrio aureus* Weibel and *Vibrio flavescens* Weibel. From sewage.

*Vibrio fuscus* Stamer. (Jour. Bact., 42, 1941, 540.) Marine agar-digesting vibrio.

*Vibrio gauducheau* Hauduroy et al. (Gauducheau, in Violle, Le Choléra, Masson édit., 1919; Hauduroy et al., Dict. d. Bact., 1937, 543.) From the blood of a fever patient. Resembles *Vibrio comma*.

*Vibrio ghinda* Pfeiffer. (Pasquale,

Gior. med. d. r. esercito, 1891; Pfeiffer, in Flugge, Die Mikroorganismen, 2, 1896, 590; *Microspira ghinda* Migula, Syst. d. Bakt., 2, 1900, 996.) From water.

*Vibrio grossus* (Migula) Ford. (Vibrio No. 1, Kutscher, Ztschr. f. Hyg., 20, 1895, 46; *Microspira grossa* Migula, Syst. d. Bakt., 2, 1900, 1012; Ford, Textb. of Bact., 1927, 343.) From liquid manure.

*Vibrio halobicus desulfuricans* Horowitz-Wlassowa and Sonntag. (Arb. a. d. Staatl. wissenschaft. Nahrungsmittel-Institut 1931 (Russian); see Ztschr. f. Unters. d. Lebensm., 62, 1931, 597.) A halophilic vibrio found in salted sardines, anchovies and other marine fish.

*Vibrio helcogenes* Fischer. (Cent. f. Bakt., 14, 1894, 73; *Microspira helcogenes* Migula, Syst. d. Bakt., 2, 1900, 978.) From descriptions, indistinguishable from *Vibrio proteus* according to Chester, Man. Determ. Bact., 1901, 339. From feces.

*Vibrio hyos* Ford. (Vibrio No. 3, Kutscher, Ztschr. f. Hyg., 20, 1895, 46; *Spirillum mobile* Migula, Syst. d. Bakt., 2, 1900, 1020; Ford, Textb. of Bact., 1927, 342.) Isolated from liquid manure.

*Vibrio iners* Besson, Ranque and Senez. (Compt. rend. Soc. Biol. Paris, 79, 1918, 1097.) From the feces of persons having dysentery.

*Vibrio intermedius* (Migula) Ford. (Group V, No. 9 of cholera-like vibrios, Kutscher, Ztschr. f. Hyg., 20, 1895, 481; *Microspira intermedia* Migula, Syst. d. Bakt., 2, 1900, 967; Ford, Textb. of Bact., 1927, 342.) Possibly identical with *Vibrio berolinensis* Neisser. From water.

*Vibrio ivanoff* Pfeiffer. (Ivanoff, Ztschr. f. Hyg., 15, 1893, 134; Pfeiffer, in Flugge, Die Mikroorganismen, 2, 1896, 592.) Probably a variety of *Vibrio comma* Winslow et al. according to Chester, Man. Determ. Bact., 1901, 337. From feces of a cholera patient.

*Vibrio jejuni* Jones, Orcutt and Little. (Jour. Exp. Med., 53, 1931, 853.) From small intestine of calves suffering from diarrhea.

*Vibrio kegallensis* Hauduroy et al.

(Dict. d. Bact. Path., 1937, 544) From water.

*Vibrio klimentko* Hauduroy et al (Klimentko, in Violle, Le Choléra, Masson édit., 1919; Hauduroy et al, Dict d Bact. Path., 1937, 544) Resembles *Vibrio comma*. From the intestine

*Vibrio leidenensis* Horst (Inaug Diss Leiden, 1921; abst. in Cent f Bakt I Abt., Ref., 73, 1922, 282) From a liver abscess.

\**Vibrio lingualis* Eisenberg (Zungenbelag-Vibrio. Weibel, Cent f Bakt 4, 1888, 227; Eisenberg, Bakt Diag., 3 Aufl., 1891, 212; *Spirillum linguae* Sternberg Man of Bact., 1893, 697, *Spirosoma linguale* Migula, in Engler and Prantl Die natürl. Pflanzenfam., 1. 1 a, 1895, 31) From deposit on the tongue

*Vibrio lisabonensis* Pestana Betten-court. (Cent. f. Bakt., 16, 1891, 101) According to Chantemesse identical, or nearly so, with *Vibrio proteus* From descriptions, indistinguishable from *Vibrio proteus* according to Chester, Man. Determ. Bact., 1901, 339 From feces of a cholera patient.

*Vibrio malarioria* Kalmiņš (Latvijas Universitātes Raksti, Serija I, No 11, 1930, 250.) Decomposes cellulose From soil.

*Vibrio marinus* (Russell) Ford (*Spirillum marinum* Russell, Ztschr f Hyg., 11, 1891, 165, *Microspira marina* Migula, Syst. d. Bakt., 2, 1900, 1002, Ford, Textb. of Bact., 1927, 317) From sea water. Closely resembles *Vibrio cuneatus* Gray and Thornton and *Vibrio carchedi* Klein.

*Vibrio massanah* Pfeiffer (Pasquale, Jour. med. d. r. ezerito, 1891, Pasquale, Baumgarten's Jahresberichte, 7, 1891, 326, Pfeiffer, in Flügge, Die Mikroorganismen, 2, 1896, 589, *Microspira massanah* Migula, Syst. d. Bakt., 2, 1900, 963, *Spirillum massanah* Chester, Manual Determ. Bact., 1901, 313, *Spirillum massanah* Holland, Jour. Bact., 5, 1920, 225, *Vibrio massanah* Holland, ibid.: From feces of a cholera patient

*Vibrio mulieris* Prévot (Man de Classif. des Bact. Anaér., Paris, 1910, 84) Anaerobe From the female genital tract

*Vibrio napi* Kalmiņš (Latvijas Universitātes Raksti, Serija I, No 11, 1930, 252) Decomposes cellulose From soil

*Vibrio n'dianla* Hauduroy et al (Thiroux, in Violle, Le Choléra, Masson édit., 1919, Hauduroy et al, Dict d Bact. Path., 1937, 546) Isolated from a patient having a cholera like disease

*Vibrio pericoma* Kalmiņš (Latvijas Universitātes Raksti, Serija I, No 11, 1930, 256) Decomposes cellulose From soil

*Vibrio polymorphus* Prévot (Spirochete B, Repaci, Ann. Inst. Past., 26, 1912, 544, *Vibrio pseudospirochaeta* B, Weinberg, Natuelle and Prévot, Les Microbes Anaérobies, 1926, 852, Prévot, Man de Classif. des Bact. Anaér., Paris, 1910, 83) Anaerobe From the buccal cavity

*Vibrio polymorphus* var. *petritiche* Prévot (Spirochete C, Repaci, Ann. Inst. Past., 26, 1912, 548, *Vibrio pseudo-spirochaeta* C, Weinberg, Natuelle and Prévot, Les Microbes Anaérobies, 1926, 851, Prévot, Man de Classif. des Bact. Anaér., Paris, 1910, 84) Anaerobe From the buccal cavity

*Vibrio portuensis* (Migula) Ford (Der portuenser Vibrio Jorge, Cent f Bakt., I Abt. 19, 1896, 277, *Microspira portuensis* Migula Syst. d. Bakt. 2, 1900, 1007, Ford Textb. of Bact., 1927, 351) From water

*Vibrio prima* Kalmiņš (Latvijas Universitātes Raksti, Serija I, No 11, 1930, 255) Decomposes cellulose From soil

*Vibrio pseudospirochaeta* Prévot (Spirochete A, Repaci, Ann. Inst. Past., 26, 1912, 539, *Vibrio pseudospirochaeta* A, Weinberg, Natuelle and Prévot, Les Microbes Anaérobies, 1926, 849, Prévot, Man de Classif. des Bact. Anaér., Paris, 1910, 83) Anaerobe From the buccal cavity

*Vibrio patridae* Prévot (Vibrio C, Repaci, Compt. rend Soc. Biol. Paris,

\* See *Neocardia lingualis* Chalmers and Chantemesse

1909, 630; Prévot, Man. de Classif. des Bact. Anaér., Paris, 1940, 83.) Anaerobe. From the buccal cavity.

*Vibrio pyogenes* (Doerr) Lehmann and Neumann. (Eiterspirillum, Mezinescu, Cent. f. Bakt., I Abt., Orig., 35, 1904, 201; *Spirillum pyogenes* Doerr, Cent. f. Bakt., I Abt., Orig., 38, 1905, 15; Lehmann and Neumann, Bakt. Diag., 4 Aufl., 2, 1907, 493.) From pus in a case of pyelitis calculosa. Non-motile.

*Vibrio ranicula* Kalniņš. (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 248.) Decomposes cellulose. From soil.

*Vibrio rigensis* Kalniņš. (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 254.) Decomposes cellulose. From soil.

*Vibrio rubicundus* Gotttron et al. (Gotttron, Weaver and Sherago, Jour. Bact., 43, 1942, 61.) From a trickling filter

*Vibrio septicus* Kolle. (Kolle and Schumann in Kolle and Wassermann, Handb. d. path. Mikroorg., 2 Aufl., 4, 1912, 101.) Identical with *Vibrio comma* culturally and morphologically. From a cholera-like disease.

*Vibrio smithii* (Migula) Ford (Smith, Cent. f. Bakt., 10, 1891, 177; *Microspira smithii* Migula, Syst. d. Bakt., 2, 1900, 1006; Ford, Textb. of Bact., 1927, 340.) Possibly identical with *Microspira saprophiles* Migula, *Microspira weibelii* Migula, *Microspira cloaca* Chester and *Vibrio surati* Ford. From abscesses of large intestine of swine.

*Vibrio spermatozoides* Löffler. (Cent. f. Bakt., 7, 1890, 638.) From kohlrahi infusions.

*Vibrio sputigenus* (Miller) Prévot. (*Spirillum sputigenum* Miller, Die Mikroorg. d. Mundhöhle, 2nd ed., 1892; Prévot, Man. de Classif. des Bact. Anaér., Paris, 1940, 85; not *Vibrio sputigenus* Bergey et al., Manual, 1st ed., 1923, 80.) Anaerobe. From the buccal cavity.

*Vibrio sputigenus* var. *minutissimus* Prévot. (Muhlen, Cent. f. Bakt., I

Abt., 48, 1909, 523; Prévot, Man. de Classif. des Bact. Anaér., Paris, 1940, 85.) Anaerobe. From the buccal cavity.

*Vibrio spulorum* Prévot. (Man. de Classif. des Bact. Anaér., Paris, 1940, 85.) Anaerobe. Isolated from a case of bronchitis.

*Vibrio stationis* Kalniņš. (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 239.) Decomposes cellulose. From soil.

*Vibrio stomatitis* Prévot. (Vibrien A, Repaci, Compt. rend. Soc. Biol. Paris, 1909, 630; Prévot, Man. de Classif. des Bact. Anaér., Paris, 1940, 82.) Anaerobe. From the buccal cavity.

*Vibrio subtilissimus* (Migula) Ford (*Spirillum* No. 1, Kutscher, Ztschr. f. Hyg., 20, 1895, 46; *Spirillum tenerrimum* Lehmann and Neuman, Bakt. Diag., 2, 1896, 346; *Spirillum subtilissimum* Migula, Syst. d. Bakt., 2, 1900, 1020; Ford, Textb. of Bact., 1927, 341.) Regarded by Kutscher as being probably identical with the organism found by Smith (Cent. f. Bakt., 16, 1894, 324) in swine dung. Resembles *Vibrio strictus*.

*Vibrio suis* Ford. (Vibrio No. 2, Kutscher, Ztschr. f. Hyg., 20, 1895, 46; *Spirillum coprophilum* Migula, Syst. d. Bakt., 2, 1900, 1019; not *Microspira coprophila* Migula, loc. cit., 986; Ford, Textb. of Bact., 1927, 341.) From liquid manure.

*Vibrio surati* (Lamb and Paton) Ford. (*Spirillum surati* Lamb and Paton, Arch. Int. Med., 12, 1913, 259; *Treponema surati* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 514; Ford, Textb. of Bact., 1927, 337.) Isolated from a case of vegetative endocarditis. Closely resembles *Vibrio smithii* Ford, *Microspira weibelii* Migula, *Microspira saprophiles* Migula and *Microspira cloaca* Chester.

*Vibrio synthetica* Kalniņš. (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 245.) Decomposes cellulose. From soil.

*Vibrio tenuis* Veillon and Repaci.

(Ann. Inst. Past., 26, 1912, 300) Anaerobe. From the buccal cavity.

*Vibrio terrigenus* Gunther. (Cent. f. Bakt., 16, 1894, 746; *Spirillum terrigenum* Migula, Syst. d. Bakt., 2, 1900, 1017; *Microspira terrigena* Chester, Man. Determ. Bact., 1901, 341.) Closely related to *Vibrio tonsillar* Stephens and Smith. From soil.

*Vibrio tonsillar* Stephens and Smith. (Cent. f. Bakt., 19, 1896, 929; *Microspira tonsillar* Migula, Syst. d. Bakt., 2,

1900, 1009.) Closely related to *Vibrio terrigenus* Günther. From buccal cavity.

*Vibrio toulonensis* Hauduroy et al. (Vibrien, Defressine and Cazeneuve, in Violle, Le Choléra, Masson édit., 1919; Hauduroy et al., Dict. d. Bact. Path., 1937, 547.) From mussel beds in the bay of Toulon.

*Vibrio xylitica* Kalniņš (Latvijas Universitātes Raksti, Serija I, No. 11, 1930, 232.) Decomposes cellulose. From soil

### Genus II. *Desulfovibrio* Kluver and van Niel.\*

(Cent. f. Bakt., II Abt., 94, 1936, 369, *Sporovibrio* Starkey, Arch. f. Mikrobiol., 9, 1938, 300) From M. L. *desulfo*, an abbreviation of the poorly constructed word *desulfonation*, used to indicate reduction of sulfur compounds by bacteria; *vibrio*, vibrio.

Slightly curved rods of variable length, usually occurring singly but sometimes in short chains which have the appearance of spirilla. Swollen pleomorphic forms are common. Actively motile by means of a single polar flagellum. Strict anaerobes which reduce sulfates to hydrogen sulfide. Found in sea water, marine mud, fresh water, and soil.

The type species is *Desulfovibrio desulfuricans* (Beijerinck) Kluver and van Niel.

1 *Desulfovibrio desulfuricans* (Beijerinck) Kluver and van Niel (*Bacterium hydrosulfureum ponticum* Zelinsky, Proc. Russ. Phys. and Chem. Soc., 25, 1893, 298, *Spirillum desulfuricans* Beijerinck, Cent. f. Bakt., II Abt., 1, 1893, 1; *Bacillus desulfuricans* Saltet, Cent. f. Bakt., II Abt., 6, 1900, 648; *Microspira desulfuricans* Migula, Syst. d. Bakt., 2, 1900, 1016; Kluver and van Niel, Cent. f. Bakt., II Abt., 94, 1936, 369, *Vibrio desulfuricans* Holland, Jour. Bact., 5, 1920, 225, *Sporovibrio desulfuricans* Starkey, Koninkl. Nederland Akad. v. Wetenschappen, Proc., 41, 1938, 425; also in Arch. f. Mikrobiol., 9, 1938, 268.) From M. L. present part *desulfurico*, sulfur reducing.

Slightly curved rods, 0.5 to 1.0 by 1 to 5 microns, usually occurring singly but sometimes in pairs and short chains

which cause them to look like spirilla. Swollen pleomorphic forms are common. Older cells appear black due to precipitated ferric sulfide. Actively motile, possessing a polar flagellum Gram-negative. Stains readily with carbol fuchsin.

Grows best in freshwater media. Fails to develop in sea water upon initial isolation.

Produces opalescent turbidity in absence of oxygen in mineral media enriched with sulfate and peptone.

Media containing iron salts blackened. Bacteria found associated with precipitated ferrous sulfide.

Peptone-glucose agar colonies (in absence of air): Small, circular, slightly raised, dull, entire, soft in consistency.

Gelatin not liquefied

Peptone, asparagine, glycine, alanine, aspartic acid, ethanol, propanol, butanol,

\* Prepared by Dr. Claude E. ZoBell, Scripps Institution of Oceanography, La Jolla, California, Jan., 1943.

glycerol, glucose, lactate, succinate and malate known to be utilized as hydrogen donors.

Produces up to 500 ml.  $H_2S$  per liter

Nitrites not produced from nitrates.

Reduces sulfate to hydrogen sulfide. Also reduces sulfites, sulfur, thiosulfates and hyposulfites.

Optimum pH 6 to 7.5, limits pH 5 to 9

Optimum temperature 25 to 30° C.

Maximum 35 to 40° C.

Anaerobic.

Habitat: Soil, sewage, water.

2 *Desulfovibrio aestuarii* (van Delden) *comb. nov.* (*Microspira aestuarii* van Delden, Cent f. Bakt., II Abt., 11, 1904, 81; *Vibrio desulfuricans* (halophilic strain) Baars, Over Sulfaat-reductie door Bakterien, Diss. Delft, 1930, 164 pp.) From Latin, *aestuarium*, estuary

Morphologically indistinguishable from *Desulfovibrio desulfuricans* described above, although it has a greater tendency to pleomorphism, and is slightly larger. Motile, possessing a polar flagellum. Gram-negative

Grows preferentially in media prepared with sea water or 3 per cent salt mineral solution enriched with sulfate and peptone. According to Baars (*loc cit.*) the marine species can be acclimatized to tolerate hypotonic salt solutions but Rittenberg (Studies on Marine Sulphate-Reducing Bacteria, Thesis, Univ. of Calif., 1941, 115 pp.) was unable to confirm this observation. Likewise Rittenberg was unable to acclimatize *D. aestuarii* to tolerate temperatures exceeding 45° C or to produce endospores.

Produces faint turbidity in absence of oxygen in sea water enriched with sulfate and peptone. Organisms most abundant in sediment

Agar colonies Small, circular, slightly raised, darker centers, entire, soft consistency.

Gelatin not liquefied.

Peptone, asparagine, glycine, alanine, glucose, fructose, ethanol, butanol,

glycerol, acetate, lactate and malate known to be utilized in presence of sulfate.

Reduces sulfate to hydrogen sulfide. Also reduces sulfites, sulfur, thiosulfates and hyposulfites.

Produces up to 950 ml.  $H_2S$  per liter.

Nitrites not produced from nitrates.

Optimum temperature 25° to 30° C. Maximum 35° to 40° C.

Optimum pH 6 to 8, limits pH 5.5 to 8.5.

Anaerobic.

Habitat: Sea water, marine mud, brine and oil wells.

3. *Desulfovibrio rubentschickii* (Baars) *comb. nov.* (*Vibrio rubentschickii* Baars, Over Sulfaat-reductie door Bakterien, Diss. Delft, 1930, 164 pp.) Named for L. Rubentschick.

Slightly curved rods, 0.5 to 1.0 by 1 to 5 microns, usually occurring singly, sometimes in pairs and short chains. Actively motile, possessing a polar flagellum. Gram-negative. Morphologically indistinguishable from *Desulfovibrio desulfuricans*.

Reduces sulfate to hydrogen sulfide. Also reduces sulfites, sulfur, thiosulfates and hyposulfites.

Culturally and physiologically like *D. desulfuricans* except that *D. rubentschickii* utilizes propionic acid, butyric acid, valeric acid, palmitic acid, stearic acid, galactose, sucrose, lactose and maltose.

Anaerobic.

Habitat: Soil and ditch water.

Appendix: The following species has also been regarded as belonging in this genus.

*Vibrio thermodesulfuricans* Elion (Cent f. Bakt., II Abt., 63, 1924, 58), *Vibrio desulfuricans* (thermophilic strain) Baars, Over Sulfaat-reductie door Bakterien, Diss. Delft, 1930, 164 pp.; *Sporovibrio desulfuricans* Starkey (Koninkl. Nederland. Akad. u. Wetenschapen, Proc., 41, 1938, 425, also see Arch. f.

Microbiol., 9, 1933, 268.) A thermophilic sulfate-reducing anaerobe which grows at 30 to 65°C. and which, according to Starkey, produces endospores. Elion described *Vibrio thermodesulfuricans* (Cent. f. Bakt., II Abt., 63, 1924, 58) which grows at temperatures no lower than 30 to 40°C. and has an optimum of 55°C. Morphologically it is much like *Desulfovibrio desulfuricans* and *D. aestuarii* although the thermophilic form is shorter, more rod-like, less motile and more pleomorphic. According to Baars (loc. cit.), *Vibrio thermodesulfuricans* Elion can be acclimatized to grow at lower temperatures and it is found abundantly in environments where the temperature has never been as high as 30°C. This observation is confirmed by Starkey (Arch. f. Microbiol., 9, 1933, 268) who found further that the thermophilic form found in nature or developed by acclimatization to higher temperatures

produces endospores. However, spore-formation appears to be the exception rather than the rule. The pleomorphic, peritrichous, sporogenous, sulfate-reducer is more rod-like than the asporogenous cultures and many cells of the sporogenous cultures are Gram-positive whereas asporogenous cultures of *Desulfovibrio desulfuricans* are Gram-negative, all of which leaves a question whether the sporogenous sulfate-reducer is a *Bacillus* or a *Desulfovibrio*. Rittenberg (Studies on Marine Sulfate-reducing Bacteria, Thesis, Univ. Calif., 1941, 115 pp.) was unable to adapt the marine sulfate reducer to grow at low salinities or at high temperatures, nor could it be induced to form spores.

*Desulfovibrio halohydrocarbonoclasticus* Zobell (U. S. Patent No. 2,413,278; Science News Letter, Jan. 11, 1947) From oil bearing rocks

### Genus III. *Cellvibrio* Winogradsky.\*

(Ann. Inst. Pasteur, 43, 1929, 577) From M. L. cell, an abbreviation for cellulose, *vibrio*, *vibrio*.

Long slender rods, slightly curved, with rounded ends, show deeply staining granules which appear to be concerned in reproduction. Monotrichous. Most species produce a yellow or brown pigment with cellulose. Oxidize cellulose, forming oxycellulose. Growth on ordinary culture media is feeble. Found in soil.

The type species is *Cellvibrio ochraceus* Winogradsky.

#### Key to the species of genus *Cellvibrio*.

- I. No growth on glucose or starch agar.
  - A. Ochre-yellow pigment produced on filter paper.
    1. *Cellvibrio ochraceus*.
- II. Growth on glucose and starch agar
  - A. Poor growth on starch agar.
    1. Cream-colored pigment which becomes brown with age is produced on filter paper.
      2. *Cellvibrio flavescens*.
  - B. Abundant growth on starch agar.
    1. Scanty growth on glucose agar
      - a. Intense yellow pigment produced on filter paper.
        3. *Cellvibrio fulvus*
      2. Abundant growth on glucose agar.
        - a. No pigment produced on filter paper.
          4. *Cellvibrio vulgaris*.

\* Revised by Prof. Robert S. Breed, New York State Experiment Station, Geneva, New York, Sept., 1937; no change. July, 1943.

1. *Cellvibrio ochraceus* Winogradsky. (Ann. Inst. Pasteur, 43, 1929, 549, 601.) From Greek, *ôchra*, yellow ochre; M. L. like ochre, yellow.

Plump, curved rods with rounded ends, 2.0 to 4.0 microns long, rarely occurring as spirals. Chromatic granule frequently found in center. Motile with a single flagellum. Gram-negative.

Produces diffuse, light ochre-colored, mucilaginous colonies on cellulose silica gel medium.

No action or growth on plain agar. No growth on peptone, glucose, starch or tragacanth gum agar.

Filter paper streaks: Entire paper colored ochre-yellow in 48 hrs.

Aerobic, facultative.

Optimum temperature 20°C.

Distinctive character: Rapid ochre-colored growth.

Habitat: Soil. Disintegrates vegetable fibers.

2 *Cellvibrio flavescens* Winogradsky. (Ann. Inst. Pasteur, 43, 1929, 603.) From Latin, part. adj. of *flavescere*, to turn yellow or golden.

Plump, curved rods, flexuous, with rounded ends, 0.5 by 2.5 to 5.0 microns. Shows metachromatic granules. Motile with a single flagellum. Gram-negative.

Produces diffuse, cream-colored growth becoming brownish; mucilaginous colonies on cellulose silica gel medium.

Good growth on peptone agar. Colonies 1 mm in 4 days. Grows poorly on glucose, starch and gum agars.

Filter paper streaks: Almost as rapid in growth as *Cellvibrio ochraceus* and colors entire paper in 2 to 3 days.

Aerobic, facultative

Optimum temperature 20°C.

Distinctive characters. Smaller, less curved rods that grow on a greater variety of media than *Cellvibrio ochraceus*, but do not attack cellulose as readily.

Source: Isolated from a pile of old damp sawdust.

Habitat: Soil. Disintegrates vegetable fibers.

3. *Cellvibrio fulvus* Stapp and Bortels. (Culture Y, Dubos, Jour. Bact., 15, 1928, 230; Stapp and Bortels, Cent. f. Bakt., II Abt., 90, 1934, 42.) From Latin, *fulvus*, reddish yellow.

Slightly curved rods: 0.3 to 0.4 by 1.5 to 3.0 microns. Show involution forms. Motile by means of a single polar flagellum. Gram-negative.

Cellulose is decomposed. Grows on filter paper with an intense egg-yellow color which in older cultures may deepen to rust brown.

Glucose agar: Very scanty growth.

Sucrose agar: Very slight growth.

Maltose agar: Abundant yellow growth.

Lactose agar: Fairly abundant yellow growth.

Starch agar: Very abundant, bright yellow growth which later turns brown.

Nutrient broth: No growth.

Temperature relations: Optimum 25° to 30°C. Minimum 5°C. Maximum 32° to 35°C. No growth at 37°C. Thermal death point 39° to 40°C.

Aerobic.

Source: Isolated from forest soil in Germany and from soil in the United States.

Habitat: Widely distributed in soils.

4. *Cellvibrio vulgaris* Stapp and Bortels. (Culture Co, Dubos, Jour. Bact., 15, 1928, 230; Stapp and Bortels, Cent. f. Bakt., II Abt., 90, 1934, 44.) From Latin, *vulgaris*, common.

Curved rods: 0.3 by 2.9 to 4.0 microns. Shows involution forms. Motile by means of a single polar flagellum. Gram-negative.

Cellulose is decomposed. Grows on filter paper without the formation of pigment.

Glucose agar: Abundant growth. No pigment.

Sucrose agar: Abundant slightly yellow growth.

Maltose agar: Abundant yellowish growth.

Lactose agar: Very heavy growth

Starch agar: Very abundant yellowish growth.

Nutrient broth: No growth

Temperature relations: Optimum 25° to 30°C. Minimum 5°C. Maximum 32°

to 35°C. No growth at 37°C. Thermal death point 41° to 45°C.

Aerobic.

Source. Isolated from forest soil in Germany and from soils in the United States.

Habitat. Widely distributed in soils

#### Genus IV *Celluloclella* Winogradsky \*

(Ann. Inst. Pasteur, 45, 1929, 616.) From M. L. cell, an abbreviation for cellulose; Latin dim. *clella*, a small sickle

Short rods or spindles, not exceeding 20 microns in length, with pointed ends, containing metachromatic granules. Old cultures show coccal forms. Monotrichous. Oxidize cellulose, forming oxycellulose. Growth on ordinary culture media is feeble. Soil bacteria.

The type species is *Celluloclella viridis* Winogradsky

1. *Celluloclella viridis* Winogradsky (Ann. Inst. Pasteur, 45, 1929, 616.) From Latin, *viridis*, green.

Pump, small spindles, 0.7 by 2.0 microns, with rounded ends. Motile with a single flagellum. Gram negative.

Produces diffuse green, mucilaginous colonies on cellulose silica gel medium.

Filter paper streaks. Rapid spreading growth colored green in 3 days at 20°C.

Hydrocellulose agar. Growth rapid, green, variable yellowish green, mucous colonies on streaking.

No growth on peptone, glucose, starch or gum agar.

Aerobic, facultative.

Optimum temperature 20°C.

Habitat: Soil.

liguous colonies on cellulose silica gel medium.

Hydrocellulose agar. Abundant grayish growth.

No growth on peptone, glucose, starch or gum agar.

Aerobic, facultative.

Optimum temperature 20°C.

Habitat: Soil.

3. *Celluloclella fusca* Winogradsky (Ann. Inst. Pasteur, 45, 1929, 622.) From Latin *fuscus*, dark tawny.

Pump, curved spindles, 0.5 by 1.2 to 2.5 microns, with slightly pointed ends and a central chromatic granule. Motile with a single polar flagellum. Gram negative.

Produces diffuse, brownish, slightly mottled or streaked colonies on cellulose or flagellated gum.

Filter paper streak. Paper becomes a partially transparent, dry, brownish, highly gelatinous, cottony growth.

Aerobic, facultative.

Optimum temperature 20°C.

Source. Isolated from agricultural paper pulp.

Habitat. Potentially a soil organism.

\* For a full description of the family see New York Botanical Garden, Botanical Gazette, New York, Sept., 1927, no. 4, page 2, p. 1145.

Genus V. *Thiospira* Vislouch.\*

(Jour. de Microbiologie, 1, 1914, 50; *Sulfospirillum* Kluyver and van Niel, Cent. f. Bakt., II Abt., 94, 1936, 396.) From Greek, *theion*, sulfur; *speira*, coil.

Colorless, motile, slightly bent rods, somewhat pointed at the ends, with granules of sulfur within the cells and a small number of flagella at the ends.

The type species is *Thiospira winogradskyi* (Omelianski) Vislouch.

1. *Thiospira winogradskyi* (Omelianski) Vislouch. (*Thiospirillum winogradskyi* Omelianski, Cent. f. Bakt., II Abt., 14, 1905, 769; *Thiospirillum granulatum* Molisch, Cent. f. Bakt., II Abt., 33, 1912, 55; Vislouch, Jour. de Microbiologie (Russian), 1, 1914, 50; *Sulfospirillum winogradskyi* Kluyver and van Niel, Cent. f. Bakt., II Abt., 94, 1936, 397) Named for Winogradsky, the Russian bacteriologist.

Large, sulfur spirilla, somewhat pointed at the ends, 2 to 2.5 microns thick, to 50 microns long. Numerous granules of sulfur. Very motile, with one to two polar flagella.

Habitat: Curative mud.

2. *Thiospira bipunctata* (Molisch) Vislouch. (*Spirillum bipunctatum* Molisch, Cent. f. Bakt., II Abt., 33, 1912, 55; Vislouch, Jour. de Microbiologie (Russian), 1, 1914, 50.) From Latin, *bi*, two; *punctum*, points.

Small, slightly bent sulfur spirilla, markedly pointed at the ends, 6.6 by 14 microns long, 1.7 to 2.4 microns wide (in the center of the cell). Both ends are filled more or less with large volutin (metachromatic) granules. Several minute granules of sulfur are present in the clear center and sometimes at the ends. Old cells possess one flagellum at each end; young cells have a flagellum at one end.

Habitat: Sea and salt waters.

Genus VI. *Spirillum* Ehrenberg.†

(Ehrenberg, Abhandlungen d. Berl. Akad., 1830, 38; *Spirosoma* Migula, Arb. bakt. Inst. Karlsruhe, 1, 1894, 237; *Dicrospirillum* Enderlein, Sitzber. Gesell. naturf. Freunde, Berlin, 1917, 313.) From Greek, *speira*, a spiro or coil.

Cells form either long screws or portions of a turn. Volutin granules are usually present. Usually motile by means of a tuft of polar flagella (5-20) which may occur at one or both ends of the cells. Aerobic, growing well on ordinary culture media, except for one saprophyte and the pathogenic species. These have not yet been cultivated. Usually found in fresh and salt water containing organic matter.

The type species is *Spirillum undula* (Muller) Ehrenberg.

Key to the species of genus *Spirillum*.

I One micron or less in diameter.

1. Volutin granules present.

a. Slow to rapid liquefaction of gelatin.

b. Grayish to brown growth on potato.

1. *Spirillum undula*.

\* Prepared by Prof. D. H. Bergey, Philadelphia, Penn., October, 1922.

† Revised by Prof. D. H. Bergey, Philadelphia, Pennsylvania, April, 1937; further revision by Prof. Robert S. Breed, New York State Experiment Station, Geneva, New York, June, 1943, based on Monograph by Giesberger, Inaug. Diss., Utrecht, Nov. 30, 1936.

bb. Light yellowish-orange growth on potato.

2. *Spirillum serpens*.

aa. No liquefaction of gelatin Of small size (0.5 micron in diameter).

b. Colonies on agar white becoming brownish black and slightly wrinkled

3. *Spirillum stersonii*

bb. Colonies on agar white and smooth.

4. *Spirillum tenue*.

2 No volutin granules observed.

b. Single flagellum

5. *Spirillum virginianum*.

bb. Tuft of flagella

6. *Spirillum minus*.

II. Over one micron in diameter.

1. Grows poorly on peptone agar and potato.

7. *Spirillum kutschera*.

2 Not positively known to have been cultivated on artificial media. Very evident volutin granules

8. *Spirillum volutans*.

3. Cells more or less deformed by fat drops.

9. *Spirillum lipoferum*.

1. *Spirillum undula* (Müller) Ehrenberg. (*Vibrio undula* Müller, *Animalcula infusoria et marina*, 1786; Ehrenberg, *Infusionstierchen*, 1838; *Spirillum undula minor* Kutscher, *Cent. f. Bakt.*, Abt., 18, 1893, 614.) From Latin, *undulatus*, wave-like.

Stout threads, 0.9 micron in diameter, with one-half to three turns. The wave lengths are 6 microns. Width of spiral, 0 microns. Tufts of three to nine flagella at each pole. Volutin granules present. Gram-negative.

Gelatin colonies: The surface colonies are circular, granular, greenish-yellow, entire

Gelatin stab: Thick, white, rugose surface growth Very slow liquefaction. Agar colonies: Grayish-white, smooth Broth: Turbid.

Potato: Grayish-brown growth.

Indole not formed

Catalase positive.

Nitrites not produced from nitrates.

Aerobic, facultative.

Optimum temperature 25°C.

Cohn (*Beitrage z. Biol. d. Pflanzen*, I, left 2, 1875, 132) reports that he could

not distinguish this organism from *Vibrio prolifer* Ehrenberg.

Habitat: Putrid and stagnant water.

2. *Spirillum serpens* (Müller) Winter. (*Vibrio serpens* Müller, *Animalcula infusoria et marina*, 1786, 43; Winter, in Rabenhorst's *Kryptogamen-Flora*, I, Die Pilze, 1834, 63) From Latin, *serpens*, serpent

Long, curved rods with two to three wave-like undulations, 0.8 to 1.0 micron in diameter; wave length, 8 to 9 microns. Width of spiral 1.5 to 1.8 microns. Volutin granules in cytoplasm. Motile, possessing tufts of flagella at both poles. Gram-negative

Gelatin colonies: Yellowish to brownish, granular, entire.

Gelatin stab: Yellowish surface growth. Slow liquefaction

Agar colonies: Heavy cream-colored growth.

Agar slant: Grayish, with yellowish center, granular, entire.

Broth: Turbid.

Litmus milk: Unchanged.

Potato: Clear orange-yellow growth

Indole not formed.

Catalase positive.

Nitrites not produced from nitrates.

Aerobic, facultative.

Optimum temperature 35°C.

Habitat: Stagnant water.

3. *Spirillum Itersoni* Giesberger. (Inaug. Diss., Utrecht, 1936, 46 and 57.) Named for van Iterson, the Dutch bacteriologist.

The smallest of the spirilla isolated from water. First observed by van Iterson (Proc. Kon. Akad. v. Wetensch. Amsterdam, 5, 1902, 685).

Small spirals, 0.5 micron in diameter. Wave length, 3 to 3.5 microns. Spiral width, 1 to 1.5 microns. Motile with bipolar tufts of flagella. Gram-negative.

Grows readily on peptone agar. White colonies becoming brownish black, and slightly wrinkled.

Gelatin stab: No liquefaction.

Brownish-orange growth on potato.

Volutin granules may be present.

Catalase is produced.

Acid from glucose, fructose, ethyl alcohol, n-propyl alcohol, n-butyl alcohol, and glycerol. Utilizes acetic, propionic, n-butyric, tartaric, fumaric, lactic, citric, and succinic acids.

Grows well in peptone broth. Also utilizes ammonia compounds.

Anaerobic growth in the presence of nitrates when organic or ammonia nitrogen is also available.

Optimum temperature: 30°C.

Source: Isolated from water.

Habitat: Water.

4. *Spirillum tenue* Ehrenberg. (Infusionstierchen, 1838; see Bonhoff, Arch. f. Hyg., 26, 1896, 162.) From Latin, *tenuus*, thin.

Slender spirals. Diameter 0.7 micron. Wave lengths 4.5 to 5.0 microns. Width of spiral 1.5 to 1.8 microns.

Actively motile in peptone water with tufts of flagella at each pole. Volutin granules present. Gram-negative.

Agar colonies: White, smooth.

Peptone agar slant: Heavy growth.

Gelatin stab: No liquefaction.

Catalase positive.

Potato: Light brown growth.

Acid from glucose and fructose. Slight acid from several other sugars and glycerols. Utilizes salts of acetic, propionic, n-butyric, tartaric, lactic, citric, malic, and succinic acids.

Ammonia compounds are used as a source of nitrogen.

Optimum temperature, 30°C.

Source: Found in putrefying vegetable matter.

Habitat: Putrefying materials.

5. *Spirillum virginianum* Dimitroff. (Jour. of Bact., 12, 1926, 19.) From M. L. genitive of Virginia.

Spirals consisting of  $\frac{1}{2}$  to 3 complete turns in young cultures, older cultures showing 7 turns. 0.6 to 0.9 by 3 to 11 microns. Motile with a single polar flagellum on one or both ends. Gram-negative.

Gelatin colonies: Entire, convex, circular, moist, colorless.

Gelatin stab: Growth along entire stab. No liquefaction. (Dimitroff, *loc. cit.*) Active liquefaction. (Giesberger, Inaug. Diss., Utrecht, 1936, 65.)

Agar colonies: Dew drop, convex, entire, moist, colorless.

Agar slant: Dew drop, isolated colonies.

Broth: Cloudy, no flocculation.

Uschinsky's protein-free medium: Abundant growth.

Litmus milk: No growth.

Loeffler's blood serum: Convex, isolated dew drop colonies. No liquefaction.

Lead acetate agar: No H<sub>2</sub>S.

Voges-Proskauer and methyl red negative.

No volutin granules observed (Giesberger, *loc. cit.*, p. 60).

Potato: No growth.

Indole not formed.

Nitrites not produced from nitrates.

No acid or gas from carbohydrates.

(Dimitroff, *loc. cit.*). Utilizes lactates and citrates (Giesberger, *loc. cit.*)

Aerobic, facultative.

Optimum temperature 35°C.

Source: Isolated from mud on an oyster shell.

Habitat. Probably muddy bottom of brackish water.

6. *Spirillum minus* Carter. (Carter, *Sci. Mem. Med. Officers Army India*, 3, 1887, 45; *Spirillum minor* Carter, *ibid.*; *Spirochaeta laverani* Breinl and Kinghorn, *Mem. Liverpool Sch. Trop. Med.*, 21, 1906, 55; *Spirochaeta muris* Wenyon, *Jour. Hyg.*, 6, 1906, 580, *Spirochaeta muris* var. *virginiana* MacNeal, *Proc. Soc. Exper. Biol. and Med.*, 4, 1907, 125; *Spirochaeta muris* var. *galatziana* Mezincescu, *Compt. rend. Soc. Biol. Paris*, 66, 1909, 58; *Treponema muris* Moore, *Principles of Microbiology*, 1912, 414, *Spirochaeta morsum muris* Futaki, Takaki, Taniguchi and Osumi, *Jour. Exp. Med.*, 25, 1917, 33; *Spirochaeta petit* Row, *Ind. Jour. Med. Res.*, 5, 1917, 386, *Spirochaeta muris* Noguchi, *Jour. Exp. Med.*, 27, 1918, 584; *Spirochaeta japonica* Dujarric de la Rivière, *Ann. de Méd.*, 5, 1918, 181; *Spirochaeta morsum muris* Castellani and Chalmers, *Man. Trop. Med.*, 3rd ed., 1919, 117; *Spiroschaudinna morsum muris* Castellani and Chalmers, *ibid.*, *Spirochaeta sodoku* Troisier, 1920, according to Pettit, *Contribution à l'étude des Spirochétidés*, Vanves, II, 1928, 231, *Treponema japonicum* Brumpt, *Nouveau Traité de Médecine*, Paris, 4, 1922, 505, *Treponema morsum muris* Brumpt, *ibid.*, 506; *Treponema minor* Brumpt, *ibid.*, 507; *Treponema laverani* Brumpt, *ibid.*, 507; *Treponema sodoku* Brumpt, *ibid.*, 514; *Spirochaeta petiti* Row, *Jour. Trop. Med. and Hyg.*, 25, 1922, 361, *Treponemella muris* San Giorgi, *Pathologica rivista*, 14, 1922, 161; *Borrelia muris* Bergey et al., *Manual*, 2nd ed., 1925, 435; *Spirillum minus* var. *morsum muris* Ruys, *Cent. f. Bakt.*, I Abt., Orig., 101, 1927, 270; *Spirillum minus* var.

*muris* Ruys, *ibid.*; *Spirochaeta minor* Ford, *Textb. of Bact.*, 1927, 962; *Spirochaeta laverani* Ford, *ibid.*, 963, *Spirochaeta muris* var. *virginiana* Ford, *ibid.*, 963; *Spirochaeta morsum muris* Noguchi, in Jordan and Falk, *Newer Knowledge Bact. and Immun.*, 1928, 497; *Spirochaeta muris* Noguchi, *ibid.*) From Latin, minus, less.

Description taken from Adachi, *Jour. Exp. Med.*, 33, 1921, 617 and Giesberger, *Inaug. Diss.*, Delft, 1936, 67.

Short thick cells 0.5 by 3.0 microns, having 2 or 3 windings which are thick, regular and spiral. Actively motile by means of bipolar tufts of flagella. Gram-negative.

Has not been cultivated on artificial media

Aerobic, facultative.

Pathogenic for man, monkeys, rats, mice and guinea pigs

This species is regarded by some as a spirochaete. Because of its habitat and wide distribution it has been described under many different names. It is possible that some of these names indicate varieties or even separate species. See Beeson (*Jour. Amer. Med. Assoc.*, 123, 1943, 332) for important literature.

Source: Found in the blood of rats and mice.

Habitat: The cause of rat-bite fever. Widely distributed.

7. *Spirillum kutscheri* Migula. (*Spirillum undula majus* Kutscher, *Cent. f. Bakt.*, I Abt., 18, 1895, 614; Migula, *Syst. d. Bakt.*, 2, 1900, 1021) Named for Kutscher, the German bacteriologist who first isolated the organism

Stout threads, 1.5 microns in diameter. Wave lengths 10.5 to 12.5 microns. Width of spiral, 3 to 4.5 microns. May lose their spiral form on continued cultivation. Motile with tufts of flagella at the poles. Gram-negative.

Gelatin colonies: Transparent, round, surface colonies. Deep colonies, dark brown.

Gelatin stab: Slow liquefaction.

Agar colonies grow poorly, granular. Deep colonies yellowish-green to dark brown.

Agar slant: Delicate, transparent growth.

Potato: Limited growth.

Volutin present.

Catalase positive.

Utilizes malic and succinic acids.

Grows well on peptone broth. Also utilizes ammonia compounds.

Optimum temperature, 22° to 27°C.

Source: Isolated from putrid materials and liquid manure.

Habitat: Putrefying liquids.

8. *Spirillum volutans* Ehrenberg. (Prototype, *Vibrio spirillum* Muller, *Animalcula infusoria*, 1786; Ehrenberg, *Die Infusionstierchen als Vollkommene Organismen*, 1838 ) From M. L. volutin.

Spirals 1.5 microns in diameter. Wave length, 13 to 15 microns, width of spiral, 4 to 5 microns. The largest of the spirilla. Slightly attenuated ends. Motile, possessing a tuft of ten to fifteen flagella at each pole. Dark granules of volutin in the cytoplasm. Gram-negative.

Migula (Syst. d. Bakt., 2, 1900, 1025) reports that this species has not been cultivated on artificial media, and that the cultures so described by Kutscher (Ztschr. f. Hyg., 20, 1895, 58) are of a different species which Migula names *Spirillum giganteum*. Vahle (Cent. f. Bakt., II Abt., 25, 1910, 237) later describes the cultural characters of an organism which he regards as identical with Kutscher's organism. Giesberger (Inaug. Diss., Delft, 1936, 65) saw what he felt was the true *Spirillum volutans* but could not cultivate it.

Optimum temperature 35°C

Habitat: Stagnant water.

9. *Spirillum lipoferum* Beijerinck (*Azotobacter spirillum* Beijerinck, Kon. Akad. Wetensch. Amsterdam, 30, 1923, 431 quoted from Giesberger, Inaug. Diss., Delft, 1936, 24; *Spirillum lipoferum* Beijerinck, Cent. f. Bakt., II Abt., 68, 1925, 353; *Chromatium lipoferum* Bergey et al., Manual, 3rd ed., 1930, 531.) From Greek, *lipos*, fat; Latin, *fero*, to bear.

Curved cells with one-half to one spiral turn, containing minute fat droplets. These may deform the cells. Motile with lophotrichous flagella. Gram-negative.

Calcium malate agar colonies: Circular, small, transparent, dry. The malate is oxidized to calcium carbonate. Cells contain fat drops.

Peptone agar colonies: More abundant development. Cells lack fat drops and are typically spirillum in form.

Glucose peptone broth: Cells actively motile with large fat drops.

Fixes atmospheric nitrogen in partially pure cultures, i.e., free from *Azotobacter* and *Clostridium* (Beijerinck, loc. cit.). Schröder (Cent. f. Bakt., II Abt., 85, 1932, 17) failed to find fixation of nitrogen when she used cultures derived from a single cell.

Aerobic.

Optimum temperature 22°C.

Beijerinck regards this as a transitional form between *Spirillum* and *Azotobacter*. Giesberger (loc. cit., p. 64-65) thinks it a *Vibrio*.

Habitat: Garden soil.

Appendix: \* The following additional species have been mentioned in the literature. Many are inadequately described. Some may not belong here.

\* Prepared by Mr Wm. C. Haynes, New York State Experiment Station, Geneva, New York, Jan., 1939; Revised by Capt. Wm. C. Haynes, Sn. C., Fort Bliss, Texas July, 1943.

*Spirella canis* Duboseq and Lebailly (Compt. rend. Acad. Sci. Paris, 154, 1912, 835.) From the stomach of a dog.

*Spirillum amyliiferum* Van Tieghem (Bull. Soc. botan. de France, 26, 1879, 65) Said to produce spores Ford (Textb. of Bact., 1927, 361) thinks this organism was probably a spirochaete because of its mode of division. Found in frog spawn fungus of sugar factories

*Spirillum attenuatum* Warming (Om nogle ved Danmarks Kyster levende Bakterier. Kjobenhavn, 1876; *Spirosoma attenuatum* Migula, Syst. d. Bakt., 2, 1900, 959.) Ford (*loc cit.*, 363) states that this incompletely described organism would now be regarded either as a spirillum or as a spirochaete From sea coast of Denmark.

*Spirillum cardiopyrogenes* Sardjito (Geneesk. Tijdschr. voor Ned-Indie, 72, 1932, 1359; *ibid.*, 73, 1933, 822.) From blood of a patient with pericarditis

*Spirillum colossus* Errera (Rec. trav. bot. Bruxelles, 5, 1902; Abst. in Cent. f. Bakt., II Abt., 9, 1902, 608) A giant form isolated from brackish sea water. Probably the same as *Spirillum volutans* Ehrenberg.

*Spirillum concentricum* Kitasato. (Cent. f. Bakt., 3, 1888, 73) Found in putrefying blood.

*Spirillum crassum* Veillon and Repaci. (Ann. Inst. Past., 26, 1912, 300) Described as having peritrichous flagella From lung lesions in human tuberculosis

*Spirillum endoparagoticum* Sorokin. (Cent. f. Bakt., 1, 1887, 465) Described as producing spores in old cultures. From rain water in bark of poplar tree.

*Spirillum giganteum* Migula. (*Spirillum volutans* Kutscher, Ztschr. f. Hyg., 20, 1895, 58; Migula, Syst. d. Bakt., 2, 1900, 1025.) From putrefying liquids

*Spirillum hachaizae* Kowalski. (Cent. f. Bakt., 16, 1891, 324; *Spirillum hachaizicum* Kowalski, *ibid.*, 324; *Spirochaeta hachaizae* Castellani and Chalmers, Man. Trop. Med., 1st ed., 1910, 316; *Treponema*

*hachaizae* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 495.) Found in feces of cholera patients and also of healthy individuals.

*Spirillum kolkwitzii* Vislouch. (Jour. de Microbiol. (Russian), 1, 1914, 50.)

*Spirillum leucomelaenum* Perty. (Zur Kenntniss kleinster Lebensformen. Berne, 1852. Also see Koch, Mitt. Kais. Gesundheitsamte, 1, 1881, 48.) From stagnant water.

*Spirillum monospora* Dobell. (Quart. Jour. Micr. Sci., 52, 1908, 121.) Described as producing spores. From large intestine of frogs and toads.

*Spirillum nigrum* Rust. (Thèse méd., Paris, 1893; see Cent. f. Bakt., I Abt., 20, 1901, 209) Strict anaerobe from pus.

*Spirillum ostreae* Noguchi. (Jour. Exp. Med., 34, 1921, 295.) From oysters.

*Spirillum periplaneticum* Kunstler and Gineste (Compt. rend. Soc. Biol. Paris, 61, 1906, 135.) From the intestine of the cockroach, *Periplaneta americana*.

*Spirillum pyogenes* Mezincescu. (Cent. f. Bakt., I Abt., Orig., 35, 1904, 201; *Spirochaeta pyogenes* Blanchard, Semaine Méd., 26, 1906, 1; *Treponema pyogenes* Brumpt, Nouveau Traité de Médecine, Paris, 4, 1922, 511) From a case of pyelitis calculosa

*Spirillum rappin*: De Toni and Trevisan. (Spirochaete, Rappin, Contr. à l'Étude d. Bactér. de la Bouche à l'État normal, 1881, 68; De Toni and Trevisan, in Saccardo, Sylloge Fungorum, 8, 1889, 1003) From the stomach of a dog.

*Spirillum recti physeteris* Beauregard (Compt. rend. Acad. Sci. Paris, 125, 1897, 255.) From ambergris.

*Spirillum rugula* (Müller) Winter. (*Vibrio rugula* Müller, Animalcula infusoria, 1786; Cohn, Beitrage z. Biol. d. Pflanz., 1, Heft 2, 1872, 178; Bonhoff, Arch. f. Hyg., 26, 1896, 162; Winter, Die Pilze, in Rabenhorst's Kryptogamen-Flora, 1884.) Prazmowski found spores, but it is not certain his cultures were pure. Bonhoff also observed spores, but

concluded that they were due to contaminating organisms (Ford, Textb. of Bact., 1927, 360). From water.

*Spirillum sporiferum* Migula. (Syst. d. Bakt., 2, 1900, 1028.) Produces spores. The spirals in which the spore formation is beginning are like *Spirillum leucomelaenum* Perty (Ford, loc. cit., 336). Giesberger (loc. cit., p. 60) places this and other so-called spore-forming spirilla in *Sporospirillum* Orla-Jensen (Cent. f. Bakt., II Abt., 22, 1909, 340). From a bean infusion.

*Spirillum sputigenum* Miller. (Die Mikroorganismen der Mundhöhle. Leipzig, 1892, Deutsche med. Wehnschr., 32, 1906, 1 and 318.) Hoffman and Prowazek (Cent. f. Bakt., I Abt., Orig., 41, 1906, 741) claim that *Spirillum sputigenum* has peritrichous flagella. Giesberger (loc. cit., 63) places this in *Selenomonas* Prowazek (Cent. f. Bakt., I Abt., Orig., 70, 1913, 36). Muhlen (Cent. f. Bakt., I Abt., Orig., 48, 1909, 525) reports 1 to 3 flagella, the majority of the organisms having apparently a single thick flagellum (a bunch of flagella) on the concave side (Ford, loc. cit., 367). Anaerobic. From the buccal cavity.

*Spirillum stomachi* Lehmann and Neumann. (*Spirillum* Form  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$  Salomon, Cent. f. Bakt., I Abt., 19, 1896, 433; Lehmann and Neumann, Bakt. Diag., 2 Aufl., 2, 1899, 362.) Found in stomach of dog, cat and rat.

*Paraspirillum rejzdorski* Dobell. (Arch. f. Protistenk., 24, 1911, 97.) Found only

once in fresh water containing *Oscillatoria*. Flagellate flexible spiral cells described as possessing a nucleus. This may be a protozoan.

*Spirobacillus gigas* Certes. (Bull. Soc. Zool. France, 14, 1889, 322; abst. in Ann. de Microgr., 2, 1889-1890, 137.) From water.

*Vibriothrix tonsillaris* Tunnicliff and Jackson. (Organism from Actinomyces-like granules, Tunnicliff, Jour. Inf. Dis., 38, 1926, 366; Tunnicliff and Jackson, *ibid.*, 46, 1930, 12.) From tonsillar granules. May be identical with *Leptothrix asteroide* Mendel and as a Gram-negative, anaerobe may belong in *Bacteroides* according to Rosebury (Bact. Rev., 8, 1944, 202).

*Vibriothrix zeylanica* (Castellani) Castellani. (*Spirillum zeylanicum* Castellani Jour. Ceylon Branch Brit. Med. Assoc., 7, 1910, 5 and Philipp. Jour. Sci., 5, No. 2, Sect. B., Medical Sciences, July, 1910; *Vibrio zeylanicus* Castellani, 1913, *Bacillus zeylanicus* Castellani, 1913 and *Vibriothrix zeylanica* Castellani, 1917, quoted from Castellani and Chalmers, Man. Trop. Med., 3rd ed., 1919, 1069; *Spirobacillus zeylanicus* Castellani, Spagnuolo and Russo, Bull. Soc. Path. Exot., 11, 1918, 271.) Motile. Gram-negative. From cases of dysenteric enteritis in Ceylon. This is the type species of the genus *Vibriothrix* Castellani (see Castellani and Chalmers, loc. cit., 1068).

## FAMILY III. AZOTOBACTERIACEAE BERGEY, BREED AND MURRAY.\*

(Preprint, Manual, 5th ed., October, 1938, v and 71.)

Cells without endospores. Relatively large rods or even cocci, sometimes almost yeast-like in appearance. The type of flagellation in this genus has been definitely established as peritrichous Gram-negative. Obligate aerobes, usually growing in a film on the surface of the culture medium. Capable of fixing atmospheric nitrogen when provided with carbohydrate or other energy source. Grow best on media deficient in nitrogen. Soil and water bacteria.

There is a single genus.

Genus I. *Azotobacter* Beijerinck.

(Beijerinck, Cent. f. Bakt., II Abt., 7, 1901, 567; *Azotomonas* Orla-Jensen, Cent. f. Bakt., II Abt., 24, 1903, 444.)

The definition is identical with that of the family. From Gr. *azous*, not living. French, *azote*, nitrogen, Gr *baktron*, rod, stick.

The type species is *Azotobacter chroococcum* Beijerinck

1 *Azotobacter chroococcum* Beijerinck. (Cent. f. Bakt., II Abt., 7, 1901, 567 and 9, 1902, 3; *Bacillus azotobacter* Löhnis and Hanzawa, Cent. f. Bakt., II Abt., 42, 1914, 1; *Bacillus chroococcus* Buchanan, General Syst. Bact., Baltimore, 1925, 194.) From Gr. *chroa*, color; *coccus*, grain; M. L. sphere.

According to Löhnis and Smith (Jour. Agr. Res., 23, 1923, 401) *Azotobacter beijerinckii* Lipman (New Jersey Agr. Exp. Sta. Rept., 25, 1904, 247), *Azotobacter woodstownii* Lipman (*ibid.*), *Azotobacter smyrnii* Lipman and Burgess (Cent. f. Bakt., II Abt., 44, 1915, 504) and *Azotobacter hulgardii* Lipman (Science, 29, 1909, 941) are identical with *Azotobacter chroococcum*. Greene (Soil Sci., 39, 1935, 327) studied *Azotobacter chroococcum* and *Azotobacter beijerinckii* by chemical analyses and found the chemical composition of the cells to be practically identical, but different from that of *Azotobacter vinelandii* and *Azotobacter agilis*. Smith (private communication) feels that *Azotobacter beijerinckii* is a non-pigmented rough strain of *Azotobacter chroococcum*.

Grows in absence of organic nitrogen.

Rods: 2.0 to 3.0 by 3.0 to 6.0 microns, occurring in pairs and packets and occasionally in chains. The cells show three or four refractile granules. The organisms are surrounded by a slimy membrane of variable thickness, usually becoming brownish in older cultures, due possibly to the conversion of tyrosine to melanin. The coloring matter is insoluble in water, alcohol, ether and chloroform. Motile by means of numerous peritrichous flagella (Hofer, Jour. Bact., 47, 1944, 415.) Gram-negative.

Gelatin colonies: Very small, circular, yellow, granular, later becoming yellowish-brown.

Gelatin stab: Only slight growth in the stab. No liquefaction.

Mannitol agar stab: Gray, may become brownish.

Nutrient broth: No growth even in the presence of glucose, peptone utilized with difficulty.

Litmus milk: Becoming clearer in 10 to 14 days.

Potato: Glossy, barely visible, slimy

\* Revised by Dr. A. W. Hofer, New York State Experiment Station, Geneva, New York, June, 1938; further revision by Dr. A. W. Hofer, July, 1943.

to wrinkled; may become yellowish, brownish-yellow or chocolate brown.

The organism fixes atmospheric nitrogen and gives off  $\text{CO}_2$ , utilizing glucose and sucrose. Other generally used carbon compounds are fructose, maltose, mannitol, inulin, dextrin, galactose, arabinose, starch, glycerol, ethyl alcohol, acetate, butyrate, citrate, lactate, malate, propionate and succinate.

Nitrate: Improves growth in amounts less than 1 gm. per liter, greater amounts are toxic.

Fixes nitrogen moderately actively.

Chemical analysis: Four-day cultures grown upon mannitol agar (Greene, 1935), when dried, are found to contain less than 0.5 per cent of hemicelluloses, less than 20 per cent of crude protein, less than 5 per cent of ash, and more than 30 per cent of lignin-like materials. The nitrogen fraction contains less than 1 per cent of amide nitrogen, less than 1 per cent of humin nitrogen and about 1 per cent of basic nitrogen.

Aerobic

Optimum temperature  $25^\circ\text{C}$ . to  $28^\circ\text{C}$ .

Distinctive characters: Inability to grow in peptone media, even in the presence of glucose, frequent occurrence of a dark brown or black pigment.

Source: Isolated from soil

Habitat: Occurs naturally in the majority of neutral or alkaline field soils

2. *Azotobacter agile* Beijerinck (Cent. f. Bakt., II Abt., 7, 1901, 577.) From *L. agilis*, agile, quick.

In studies on the chemical composition of cells Greene (Soil Sci., 59, 1935, 327) found *Azotobacter vinelandii* Lipman (New Jersey Agr. Exp. Sta. Rept., 24, 1903, 238) to be very similar to *Azotobacter agile* Beijerinck. Smith and Löhnis (Jour. Agr. Res., 23, 1923, 401) agree and state furthermore that the two are identical; they believe also that *Azotobacter vitreum* Löhnis and Westermann (Cent. f. Bakt., II Abt., 22, 1908, 234) is another synonym of *Azotobacter agile*.

Smith (private communication) states that *Azotobacter vitreum* is a very weak growing, smooth strain of *Azotobacter agile*. Kluyver and van Reenen (Arch. Mikrobiol., 4, 1933, 299) feel that a distinction should be made between *Azotobacter agile* and *Azotobacter vinelandii*. In regard to the former, Kluyver and van den Bout (Arch. Mikrobiol., 7, 1936, 263) suggest that it be further subdivided into *Azotobacter agile* and *Azotobacter agile* var. *atypica*, the latter referring to an *Azotobacter agile* form that fails to produce pigment.

Rods: 4 to 6 microns in length, almost spherical. Actively motile by means of numerous peritrichous flagella (Hofer, loc. cit.). Some strains are reported to be non-motile. Gram-negative.

Grows in absence of organic nitrogen.

Gelatin: No liquefaction.

Mannitol agar colonies: Circular, grayish white, translucent with whitish center.

Washed agar colonies: Show slight bluish-green fluorescence.

Mannitol agar slant: Grayish, translucent, fluorescent.

Plain agar slant: Yellowish-white, smooth, glistening, translucent with opaque center.

Broth: Turbid, with sediment.

Litmus milk: Becoming clear in 10 to 14 days.

Potato: Yellowish-white, slimy, becoming yellowish-brown.

In the presence of organic acids, a greenish or reddish pigment is formed.

The organism fixes atmospheric nitrogen actively, and gives off  $\text{CO}_2$ .

Aerobic.

Chemical analysis: Four-day cultures grown upon mannitol agar (Greene, 1935), when dried, contain more than 4 per cent of hemicelluloses, more than 45 per cent of crude protein, more than 7 per cent of ash, and less than 4 per cent of lignin-like materials. The nitrogen fraction contains more than 1 per cent amide nitrogen, more than 1 per cent humin

nitrogen, and 2 per cent or more of basic nitrogen.

Optimum temperature 25°C to 28°C

Distinctive characters. Lack of a brown pigment; occasional fluorescence; growth in peptone broth containing glucose.

Source: Originally isolated from canal water at Delft.

Habitat: Occurs in water and soil

3. *Azotobacter indicum* Starkey and De. (Soil Sci. 47, 337, 1939) From *L. indicus*, of India.

Rods: Ellipsoidal, from 0.5 to 1.2 by 1.7 to 2.7 microns when grown on nitrogen free glucose agar. One of the distinctive characteristics is the presence of two large, round, highly refractive bodies in the cells, one usually at each end. Motile by means of numerous peritrichous flagella (Hofer, *loc. cit.*). Gram-negative.

The organism grows slowly but in time produces large amounts of slime

Has high acid tolerance, since it grows from pH 3 to 9.

Sucrose or glucose agar plates: Colonies are colorless, round, very much raised, and uniformly turbid, having much the appearance of heavy starch paste. After two weeks, a buff to light brown color develops.

Mannitol agar slant: Grows very poorly.

Peptone agar slant with 0.5 per cent glucose: Limited grayish growth.

Nutrient broth: No growth.

Liquid media generally: Turbidity with some sediment.

Fixes atmospheric nitrogen readily with either glucose or sucrose as source of energy.

Aerobic

Optimum temperature: 30°C.

Distinctive characters: Tolerance of acidity, wide limits of pH tolerated, abundant slime production, large globules of fat within cells.

Source: Soils of India.

Habitat: Soils

Appendix I: The relationship of the following species to the species placed in *Azotobacter* is not yet entirely clear.

#### *Genus Azotomonas* Stapp.

(Cent. f. Bakt., II Abt., 102, 1940, 18; not *Azotomonas* Orla-Jensen, Cent. f. Bakt., II Abt., 24, 1909, 481.)

Rod to coccus-shaped aerobic bacteria, motile by means of 1 to 3 polar flagella. No endospores. No fat-like reserve food granules in the cells. Form acid and gas from glucose, and other sugars and alcohols. Form indole. Chemo-heterotrophic. Many carbon compounds other than sugars used as sources of energy. Active in the fixation of atmospheric nitrogen. Live in soil. From Gr. *azous*, not living, French, *azote*, nitrogen; Greek, *monas*, a unit; M. L. monad

The type species is *Azotomonas insolita*.

*Azotomonas insolita* Stapp. (Abstracts of Communications, Third Internat. Congr. for Microbiol., Sect. VIII, 1939, 306, abst. in Proc. Soil Sci. Soc. of America, 4, 1939, 244; Cent. f. Bakt., II Abt., 102, 1940, 1.) From Latin *insolitus*, unusual.

Coccoid rods: 0.6 to 1.2 by 0.6 to 1.8

microns. Motile with one to three polar flagella Gram-negative

Gelatin: No liquefaction.

Agar slant: Glistening white growth.

Agar colonies: Flat, whitish, edge entire. Weakly fluorescent.

Broth: Strong turbidity. Sediment. Pellicle

Milk: No change.

Potato: Growth somewhat dry, not slimy, dirty gray, spreading.

Nitrites produced from nitrates.

Fixes nitrogen.

Ammonium salts utilized.

Acid and gas from adonitol, arabinose, dextrin, glucose, galactose, glycerine, inositol, lactose, fructose, maltose, manitol, mannose, raffinose, rhamnose, salicin, sorbitol, starch, sucrose and xylose.

Starch is hydrolyzed.

Hydrogen sulfide produced.

Optimum temperature 25° to 30°C.

Minimum 7° to 9.5°C. Maximum 48°C.

Good growth at 37°C. Thermal death point 60°C.

Limits of pH 3.3 to 9.5.

Aerobic.

Source: From a mixture of chopped cotton husks and rice hulls.

Habitat: Soil.

## FAMILY IV. RHIZOBIACEAE CONN.

(Jour. Bact., 36, 1938, 321.)

Cells without endospores, rod-shaped, sparsely flagellated (one polar or lateral flagellum, or 2 to 4 peritrichous ones); some species non-motile. Usually Gram-negative. One genus (*Chromobacterium*) produces a violet pigment. Grow aerobically on ordinary culture media containing glucose. Glucose and sometimes other carbohydrates are utilized, without appreciable acid formation. Saprophytes, symbionts and pathogens. The latter are usually plant pathogens forming abnormal growths on roots and stems.

*Key to genera of family Rhizobiaceae.*

- I. Cells capable of fixing free nitrogen when growing symbiotically on the roots of *Leguminosae*.

Genus I. *Rhizobium*, p 223.

- II. Either plant pathogens which attack roots or produce hypertrophies on stems, or free-living non-chromogenic soil or water forms Do not fix nitrogen.

Genus II *Agrobacterium*, p. 227.

- III. Usually free-living soil and water forms which produce a violet chromogenesis.

Genus III. *Chromobacterium*, p 231.

*Genus I Rhizobium Frank.\**

(*Phytomyza* Schroeter, in Cohn, Kryptogamen-Flora von Schlesien, 3, 1886, 134; Frank, Ber. d. deut. bot. Gesellsch., 7, 1889, 380, *Rhizobacterium* Kirchner, Beitr. z. Biol. d. Pflanzen, 7, 1895, 221; *Rhizomonas* Orla-Jensen, Cent. f. Bakt., II Abt., 22, 1909, 328). From Greek *rhiza*, root, *bios*, life

Rods: 0.5–0.9"

teroidal forms

in which acid

negative. Aerobic, heterotrophic, growing best with extracts of yeast, malt or other plant materials. Nitrates may be reduced to nitrites. Nitrites are not utilized. Gelatin is not liquefied or is very slightly liquefied after long incubation. Optimum temperature 25°C. This group is capable of producing nodules on the roots of *Leguminosae*, and of fixing free nitrogen during this symbiosis.

The type species is *Rhizobium leguminosarum* Frank

*Key to the species of genus Rhizobium.*

1. Litmus milk alkaline.

- a. Formation of serum zone in milk

- b. Moderate growth, slight acid reaction on yeast water agar plus mono-, di- and trisaccharides.

- c. Causes formation of root nodules on species of the genera *Lathyrus*, *Pisum*, *Vicia* and *Lens*. Bacteroids irregular with x, y, star-, and club-shaped forms; rods peritrichous when young.

1. *Rhizobium leguminosarum*.

- cc. Causes formation of root nodules on *Phaseolus vulgaris*, *P. multiflorus* and *P. angustifolius*. Bacteroids vacuolated rods, few branched forms, young cells peritrichous.

2 *Rhizobium phaseoli*.

ccc. Causes formation of nodules on species of genus *Trifolium*. Bacteroids pear-shaped, swollen, vacuolated. Pentoses usually not fermented.

3. *Rhizobium trifolii*.

aa. No serum zone formed in milk.

b. Scant growth, alkaline reaction on yeast water agar plus most carbohydrates.

c. Causes formation of nodules on species of genus *Lupinus* and on *Ornithopus sativus*. Bacteroids vacuolated, rods seldom branched.

4. *Rhizobium lupini*.

cc. Causes formation of nodules on *Soja max*. Bacteroids long slender rods, seldom vacuolated or branched; young cells monotrichous.

5. *Rhizobium japonicum*.\*

2. Litmus milk acid.

a. Formation of serum zone in milk.

b. Moderate growth, slight acid reaction on yeast water agar plus mono-, di- and trisaccharides.

c. Causes formation of root nodules on species of the genera *Melilotus*, *Medicago*, and *Trigonella*. Bacteroids club-shaped, branched, young cells peritrichous.

6. *Rhizobium meliloti*.

1 *Rhizobium leguminosarum* Frank emend. Baldwin and Fred. (Frank, Landwirtschaftliche Jahrbücher, 19, 1890, 563; *Rhizobium polymorphum* Dangeard, *Rhizobium fabae* Dangeard, Le Botaniste, Sér. 16, 1926, 192-194; Baldwin and Fred, Jour. Bact., 17, 1929, 146.) From Latin, of the legume family (*Leguminosae*).

Naturreiche. 2 Theil, Botanik, III Abt., Kryptogamen, Sec. 914, 1877, 1944; *Schinzia leguminosarum* Frank (all species), Bot. Ztg., 37, 1879, 377; *Phytomyza leguminosarum* Schroeter (all ex-

NOTE: The following binomials have been used for species of this genus. The names given were used by their authors to cover one or more of the species here recognized as belonging to the genus *Rhizobium*. Where a question mark (?) is used it indicates that the species was too poorly described to be recognizable today. *Schinzia cellulicola* Frank, 1877 (all species) Leunis, Synopsis der drei

species), Bot. Ztg., 46, 1888, 726; *Bacillus fabae* Beijerinck (from broad bean) and *Bacillus ornithopi* Beijerinck (from seradella), Bot. Ztg., 48, 1890, 837; *Cladochytrium tuberculum* Vuillemin (all species?), Ann. Sci. Agron. Franc. et Étrang., 5, I, 1888, 193; *Bacterium radicola* Prazmowski (all species), Landw. Vers. Sta., 37, 1890, 204; *Rhizobium mutabile* Schneider (several species) *Rhizobium curvum* Schneider (?), *Rhizo-*

\* No specific name has been proposed for the organism causing the formation of nodules on plants that are members of the so-called "cowpea" group. Data showing possible inter-relationships of certain plant species of the soybean and cowpea cross-inoculation groups prompted Walker and Brown (Soil Science, 39, 1935, 221-225) to propose a consolidation of the two groups to be recognized as being inoculated by a single species, *Rhizobium japonicum*. Results obtained recently by Reid and Baldwin (Proc. Soil Sci. Soc. Amer. for 1936, 1, 1937, 219) show these inter-relationships to include the lupine group also.

*bium frankii* var. *majus* and var. *minus* Schneider (?), *Rhizobium nodosum* Schneider (?), *Rhizobium dubium* Schneider (?), Bul. Torrey Bot. Club, 19, 1892, 213, *Rhizobium sphaeroides* Schneider (?), Ber. deut. bot. Gesell., 12, 1894, 16; *Bacillus tuberigenus* Gonnermann and *Micrococcus tuberigenus* Gonnermann, Landw. Jahrb., 23, 1894, 654, 657, are thought by Fred. Baldwin and McCoy (University of Wisconsin, Studies in Science, No. 5, 1932, 140) not to be true nodule organisms and to be too poorly described to be recognizable today; *Rhizobium pasteurianum* Mazé (all species), Ann. Inst. Pasteur, 13, 1899, 146; *Pseudorhizobium ramosum* Hartleb (?) (Chem. Zeit., 24, 1900, 887) (used for noninfective culture claimed by Stutzer (Mitt. Landw. Inst. Breslau, 1, Heft 3, 1900, 63) to be genuine root nodule organism), *Rhizobium radicicola* Hiltner and Störmer (several species) and *Rhizobium beijerinckii* Hiltner and Störmer (from lupine, serradella and soy bean), Arb. Biol. Abt. f. Land-u. Forstwirtschaft a. K. Gesundheitsamte, 3, 1903, 269; *Pseudomonas radicicola* Moore (all species), U. S. Dept. Agr. Bur. Plant Ind., Bul. 71, 1905, 27, *Rhizomonas beijerinckii* Orla-Jensen and *Rhizomonas radicicola* Orla-Jensen (see Hiltner and Störmer), Cent. f. Bakt., II Abt., 22, 1909, 328; *Bacillus* or *Bacterium radicicola* Löhnis and Hansen (peritrichous species), Jour. Agr. Research, 40, 1921, 554, *Rhizobium radiculolum* Bergey et al., Manual, 1st ed., 1923, 40 (monotrichous species); *Rhizobium loti* Dangeard (from lotus), *Rhizobium simplex* Dangeard (from sainfoin), *Rhizobium torulosum* Dangeard (from Scotch broom), Le Botaniste, Sér. 16, 1926, 195-197.

Rods: 0.5 to 0.9 by 1.2 to 3.0 microns. Motile with peritrichous flagella. Bacteroids commonly irregular with x, y, star- and club-shaped forms. Vacuolate forms predominate. Gram-negative.

Growth on mannitol agar is rapid, with tendency to spread. Streak is raised,

glistening, semi-translucent, white, slimy and occasionally viscous. Considerable gum is formed.

Slight acid production from glucose, galactose, mannose, lactose and maltose. Aerobic.

Optimum temperature 25°C.

Source: Root nodules on *Lathyrus*, *Pisum* (pea), *Vicia* (vetch) and *Lens* (lentil).

Habitat: Widely distributed in soils where the above mentioned legumes are grown.

2. *Rhizobium phaseoli* Dangeard. (Le Botaniste, Sér. 16, 1926, 197.) From Latin, *phaseolus*, bean; M. L. *Phaseolus*, a generic name.

Rods. Motile with peritrichous flagella. Bacteroids are usually rod-shaped, often vacuolated with few branched forms. Usually smaller than in *Rhizobium leguminosarum* and *R. trifolii*. Gram-negative.

Growth on mannitol agar is rapid with tendency to spread. Streak inoculation is raised, glistening, semi-translucent, white, slimy. Occasionally mucilaginous but this character is not so marked as in *Rhizobium trifolii*.

Very slight acid formation from glucose, galactose, mannose, sucrose and lactose.

Aerobic.

Optimum temperature 25°C.

Source: Root nodules of *Phaseolus vulgaris* (kidney bean), *P. angustifolius* (bean) and *P. multiflorus* (scarlet runner) (Burrill and Hansen, Ill. Agr. Exp. Sta. Bul. 202, 1917, 137.)

Habitat: Widely distributed in the soils in which beans are grown.

3. *Rhizobium trifolii* Dangeard. (Le Botaniste, Sér. 16, 1926, 191.) From M. L. *Trifolium*, a generic name.

Rods: Motile with peritrichous flagella. Bacteroids from nodules are pear-shaped, swollen and vacuolated. Rarely x and y shapes. Gram-negative.

Growth on mannitol agar is rapid. The colonies are white becoming turbid with age. Frequently mucilaginous. Streak cultures transparent at first. Growth mucilaginous later flowing down the agar slant and accumulating as a slimy mass at the bottom. Produces large amounts of gum.

Slight acid production from glucose, galactose, mannose, lactose and maltose. Aerobic.

Optimum temperature 25°C.

Source: Root nodules of species of *Trifolium* (clover).

Habitat: Widely distributed in the soils where clover grows.

4. *Rhizobium lupini* (Schroeter) Eckhardt, Baldwin and Fred. (*Phylomyxa lupini*; Schroeter, in Cohn, *Kryptogamen-Flora von Schlesien*, 3, 1, 1886, 135; *Rhizobium minimum* Dangeard, *Le Botaniste*, Sér. 16, 1926, 198; Eckhardt, Baldwin and Fred, *Jour. Bact.*, 21, 1931, 273.) From Latin, *Lupinus*, lupine.

Rods: Motile with flagella 1 to 4, usually 2 or 3. Bacteroids are vacuolate rods, seldom if ever branched. Gram-negative.

Growth on yeast water, mannitol agar is scant to moderate with alkaline reaction.

Beef-peptone gelatin: Little growth with extremely slow liquefaction.

On galactose an alkaline reaction serves to differentiate *Rhizobium lupini* from all fast-growing rhizobia (*R. phaseoli*, *R. meliloti*, *R. trifolii*, and *R. leguminosarum*). An initial alkaline reaction followed more quickly by an acid reaction on rhamnose and xylose separates *R. lupini* from slow-growing *R. japonicum* and the *Rhizobium sp.* from cow pea.

In general *Rhizobium lupini* produces slight to moderate acidity on pentose sugars and no change or alkaline reaction on hexoses, disaccharides and trisaccharides.

Litmus milk: No serum zone, no reduction, and a slight alkaline reaction.

Meager growth on potato and parsnip slants, and carrot agar.

Aerobic.

Optimum temperature 25°C.

Source: Root nodules on *Lupinus* (lupine), *Serradella* and *Ornithopus*.

Habitat: Widely distributed in soils in which these legumes grow.

5. *Rhizobium japonicum* (Kirchner) Buchanan. (*Rhizobacterium japonicum* Kirchner, *Beiträge zur Biol. d. Pflanzen*, 7, 1895, 213; *Pseudomonas japonica* Löhnis and Hansen, *Bacterium japonicum* Löhnis and Hansen, *Jour. Agr. Res.*, 20, 1921, 551; *Rhizobium sojae* Dangeard, *Le Botaniste*, Sér. 16, 1926, 200; Buchanan, *Proc. Iowa Acad. Sci.*, 33, 1926, 81.) From M. L., of Japan.

Rods: Motile with monotrichous flagella. Bacteroids of nodules are long and slender with only occasional branched and swollen forms. Gram-negative.

Growth on mannitol agar is slow and scant. The streak is slightly raised, glistening, opaque, white, butyrous, with little gum formation.

Pentose sugars give better growth than the hexoses.

Little if any acid formed from carbohydrates. Acid slowly formed from xylose and arabinose.

Aerobic.

Optimum temperature 25°C.

Source: Root nodules on *Soja max* (soy bean).

Habitat: Widely distributed in soils where soy beans are grown.

6. *Rhizobium meliloti* Dangeard. (*Le Botaniste*, Sér. 16, 1926, 191.) From Greek, *melilot*, a kind of clover; M. L., *Melilotus*.

Rods: Motile with peritrichous flagella. Bacteroids club-shaped and branched. Gram-negative.

Growth on mannitol agar is fairly rapid. The streak is raised, glistening, opaque, pearly white, butyrous. Considerable gum is formed.

Acid from glucose, galactose, mannose and sucrose.

Aerobic.

Optimum temperature 25°C.

Source: Root nodules of *Melilotus* (sweet clover), *Medicago*, and *Trigonella*

Habitat: Widely distributed in soils in which these legumes grow.

NOTE: See Monograph on Root Nodule Bacteria and Leguminous Plants by E. B. Fred, I. L. Baldwin and Elizabeth McCoy, University of Wisconsin Studies in Science, Madison, No. 5, 1932, xx + 313 pp. for a more complete discussion of this group with an extensive bibliography.

### Genus II. *Agrobacterium* Conn.\*

(Jour. Bact., 44, 1942, 359) From Greek, *agrus*, a field; M.L., *bacterium*, a small rod

Small, short rods which are typically motile with 1 to 4 peritrichous flagella (if only one flagellum, lateral attachment is as common as polar). Ordinarily Gram-negative. On ordinary culture media, they do not produce visible gas nor sufficient acid to be detectable by litmus. In synthetic media, enough CO<sub>2</sub> may be produced to show acid with brom thymol blue, or sometimes with brom cresol purple. Gelatin is either very slowly liquefied or not at all. Free nitrogen cannot be fixed, but other inorganic forms of nitrogen (nitrates or ammonium salts) can ordinarily be utilized. Optimum temperature, 25° to 30°C. Habitat: Soil, or plant roots in the soil; or the stems of plants where they produce hypertrophies.

The type species is *Agrobacterium tumefaciens* (Smith and Townsend) Conn.

#### Key to the species of genus *Agrobacterium*.

- I. Plant pathogens. Produce browning of mannitol-calcium-glycerophosphate agar. Nitrate reduction weak or none
  - A. Nitrite produced from nitrate to a slight extent. Galls produced on plant roots.
    1. *Agrobacterium tumefaciens*.
    2. *Agrobacterium rhizogenes*.
    3. *Agrobacterium rubi*.
  - B. Nitrite not produced from nitrate.
    1. Pathogenic to apples
    2. Pathogenic to raspberries and blackberries.
    3. *Agrobacterium radiobacter*.
- II. Not pathogenic to plants. Produces browning in mannitol-calcium-glycerophosphate agar. Nitrate reduction vigorous, with disappearance of the nitrate
  1. *Agrobacterium tumefaciens* (Smith and Townsend) Conn. (*Bacterium tumefaciens* Erw. Smith and Townsend, Science, N. S. 25, 1907, 672, *Pseudomonas tumefaciens* Stevens, The Fungi which Cause Plant Disease, 1913, 35, *Bacillus tumefaciens* Holland, Jour. Bact., 6, 1920, 220; not *Bacillus tumefaciens* Wilson, Lancet, 1, 1919, 675; *Phytomonas tumefaciens* Bergey et al, Manual, 1st ed, 1923, 189; Conn, Jour. Bact., 44, 1942, 359) From Latin *tumefaciens*, swelling up, producing a tumor. Probable synonyms: *Bacillus ampelopsorae* Trevisan, in Saccardo, Sylloge Fungorum, 8, 1889, 933; *Bacillus ampelopsorae* Trevisan emend. Cavara, Staz. Sperim. Agara. Ital. Modena, 30, 1897, 483; see Elliott, Bact. Plant Pathogens, 1930, 235.

\* Prepared by Prof. H. J. Conn, New York State Experiment Station, Geneva, New York, September, 1943.

Among the synonyms listed in previous editions of the Manual has been *Polyomonas tumefaciens* Lieske, Cent. f. Bakt., I Abt., Orig., 108, 1928, 118. This is only a partial synonym, however, as its author described it as the cause of animal and human cancer, of which he regarded crown-gall of plants as merely a phase: for the origin of this theory, see Smith and Townsend, Sci., N.S. 25, 1907, 671, and Smith, Jour. Cancer Res., 7, 1922, 1-105.

Description taken from the following: Riker, Banfield, Wright, Keitt and Sagen, Jour. Agr. Res., 41, 1930, 507; Sagen, Riker and Baldwin, Jour. Bact., 28, 1934, 571, Hendrickson, Baldwin and Riker, Jour. Bact., 28, 1934, 597.

Rods: 0.7 to 0.8 by 2.5 to 3.0 microns, occurring singly or in pairs. Capsules. Motile with 1 to 4 flagella. Gram-negative

Agar colonies: Small, white, circular, smooth, glistening, translucent, entire.
